One section deals with the methods of preparation of the substrates used in the subsequent enzyme reactions. Descriptive methods for dealing with enzymes themselves are divided into three sections: these consider sugar activation, complex saccharide synthesis and finally the utilization of complex saccharides. All the individual processes are described by acknowledged experts in the field, and so it will be found that the best available methods are provided. Readers will find the grouping of the sugars and the techniques concerning them together particularly valuable. Thus all the systems dealing with amino sugars are provided and also, for example, all those dealing with the involvement of sugar nucleotides in the important and novel transferase systems.

Each of the sections makes fascinating reading to all concerned with any aspect of carbohydrate chemistry and biochemistry. Articles on neuraminidase and the sulphatases are particularly topical.

Excellent author and subject indexes are provided, and the book is splendidly printed and can be warmly recom-

mended to all chemists and biochemists as a source of valuable working information. The editors are to be congratulated on their timely completion of a difficult task.

M. STACEY

## ENZYMES IN THE CELL

### Enzyme Cytology

Edited by D. B. Roodyn. Pp. xx+587. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1967.) 140s.; \$25.

WHILE many biochemists have been increasingly concerned with the mechanism of biochemical processes at the molecular level, the hybrid subject of enzyme cytology attempts to get these processes into perspective with regard to the organelles which can be seen microscopically within the cell. *Enzyme Cytology* is an attempt to survey the entire field of this relatively new, but rapidly developing, subject. It is an ambitious undertaking and the fact that the book succeeds so well reflects great credit on the editor and the authors of individual chapters.

After a chapter on the general principles of the subject, there follow chapters on nuclei, mitochondria and peroxisomes, chloroplasts, lysosomes and phagosomes, membranes, ribosomes and cell sap. The layout of most of the chapters is similar, including a brief historical introduction and a critical discussion of preparative methods, followed by a survey of relevant work on the topic in question. One of the most useful features of this book is the close relationship between the results discussed and the experimental techniques, some of which still remain something of an art as de Duve points out in his introductory chapter.

Most of the authors attempt to survey the whole field without excessive emphasis on their own work, but despite the large amount of material dealt with most of the chapters remain very readable accounts and do not degenerate into lists of references. It is a tribute to the editor that duplication of material in chapters in which the topics overlap is kept to a minimum. The book also contains useful practical details on the most satisfactory ways of expressing results and concludes with a series of recommendations on nomenclature compiled by the editor which it is hoped will form a basis for a universally acceptable terminology in this subject.

One criticism of the book is that it attempts to cover so large a field that some aspects of the subject are treated only on a superficial level; for example, the discussion of the control of enzyme activity within the cell in the last chapter is so cursory that the book gains nothing from its inclusion. Shortage of space is probably responsible for several other omissions; for example, the list of enzymes of the cell sap is sketchy, and the otherwise excellent discussion of non-cyclic photosynthetic phosphorylation contains no discussion of the revised single light-reaction scheme now favoured by Arnon.

This criticism is, however, minor compared with the achievement that this book represents. It provides a good survey of a large field backed by an extensive collection of references, and although the enzyme aspects of cytology are the prime concern of the book, structural materials and non-protein components of cell organelles are not neglected. It also provides a series of very useful critical comparisons of the various methods used for the preparation and investigation of individual sub-cellular components, which makes the book a very useful reference work for methods. Finally, the book provides a large number of electron microscope pictures of the various components dealt with, which is useful, as it is all too easy for biochemists to forget about the structure of their starting materials.

The book may appear expensive, but this is partly justified by the excellence of the numerous electron microscope pictures. It is, on the whole, well produced, but there is a large number of printing errors; for example, the words "ultracentrifug alanalysis" occur twice in the same line.

This book represents a landmark in providing an overall picture of the state of knowledge in the subject of enzyme cytology and probably represents the last time that an adequate survey of the subject can be achieved within the space of a single volume. The overall high standard set by the authors will ensure that it will be widely used both as a reference work and as a textbook. It can be recommended not only to those working in the field but more widely as a readable, lively and highly informative survey of the current state of the subject of enzyme cytology.

K. F. TILTON

## SPECIAL SENSORY MECHANISMS

### Sensory Mechanisms

Edited by Y. Zotterman. (Progress in Brain Research, Vol. 23.) Pp. 225. (Amsterdam, London and New York: Elsevier Publishing Company, 1967.) 85s.

A LENGTHY and excellent review of the present state of knowledge of the sub-mammalian vertebrate olfactory system is followed by a shorter, and slightly less satisfactory, essay on the same system in mammals. Physiological mechanisms of olfaction are then discussed by Ottoson and Shepherd at somewhat greater length than in Ottoson's own contribution to the 1962 Stockholm symposium on "Olfaction and Taste", while in the next chapter, conversely, Zotterman compresses the information on gustation which he and his collaborators presented to the Stockholm symposium.

The first four chapters all concern the anatomy and physiology of chemical sense systems, and therefore hang together. They are followed by chapters on the clinical examination of vestibular function, the mathematical formulation of inner ear disorders, and finally a theory, poised between the twin peaks of ignorance and bigotry, of "protopathy, paresthesia and sensory suppressor zones".

Those seriously interested in the chemical senses will refer to the Wenner-Gren symposium on "Olfaction and Taste" (1963), also edited by Zotterman. The volume being reviewed is the result of a summer school held in 1964, and it is evident that there can be little new information on olfactory and gustatory physiology—which naturally received fuller treatment in the symposium entirely devoted to the subject. The first two chapters of the present volume are in the best Dutch tradition of comparative neuroanatomy, and form a valuable addition to the earlier symposium; it is indeed a pity that they could not have been included in it.

The chapter on the clinical investigation of vestibular function could be useful to physiologists working on intact human beings or animals, but it is difficult to see how or why it is included in the present volume. If such a stricture is to be applied to editorial policy with regard to this chapter, it is even more cogent to ask if an essay, however interesting, on the application of cybernetics to clinical otology has its right place here. The subject of the last chapter should, of course, concern all or any sensory mechanisms; it is a realm in which informed speculation may be of great value, but the operative word is informed.

The book here being reviewed is Volume 23 in a series entitled "Progress in Brain Research"; Volume 1 appeared in 1963, and Volume 27 is announced for this year. At a time when the nightmare prophecy in Ecclesiastes appears to be in the process of fulfilment—"of making many books

there is no end; and much study is a weariness of the flesh"—it seems justifiable to enquire into the purpose and function of the series in general and of this volume in particular.

Workers in any field of nervous system research will have recourse to original articles published in the several journals devoted to the appropriate disciplines. From time to time, experts gather together to hold a symposium on some particular topic. Although these symposia rarely provide new data, they are frequently productive of fertile new ideas—usually in direct proportion to the restriction of their terms of reference. Two superb recent examples are the symposium on "Olfaction and Taste" and the CIBA symposium on "Touch Heat and Pain" (1966). A few volumes in the "Progress in Brain Research" series may be classed in this category. The present volume most certainly cannot. If the first four chapters are at least cohesive, two of them are redundant—probably through no fault of their authors. The summer school from which this book originates is supposed to be for advanced students or young researchers, and may thus serve a useful purpose. One would have expected the authors of the second chapter to give advanced students details of their methodology rather than just a bald statement of their results; and the authors of the third chapter are being a little bold in implying that in all receptors a local potential change spreads electrotonically into the afferent nerve ending.

But why print a kind of serial textbook at the rate of seven volumes a year—volumes whose content and quality is so uneven, and which at this level must date so rapidly? Many scientific publishers now realize that now so many university and institutional libraries compulsively buy every purportedly esoteric book that comes off the presses, they have a captive clientèle and so presumably an assured profit. Just in case there should be any hesitation, or perhaps to lure the unsuspecting potential individual purchaser, a title which, though misleading, is not quite downright mendacious is chosen, and it is left to the eminent individual volume editor to explain it away as best he can in a preface whose brevity is evidence of his embarrassment. Were it not a spatial, didactic and financial waste, it would be amusing to contemplate Parkinson's law in the particular case whereby the number of books published increases as the square of the number of libraries constrained to purchase them.

DAVID BOWSHER

## POISON ON THE FARM

### Garner's Veterinary Toxicology

Third edition. Revised by E. G. C. Clarke and Myra L. Clarke. Pp. 477. (London: Baillière, Tindall and Cassell, Ltd., 1967.) 60s. net.

This is an excellent reference work and fully maintains the tradition set by previous editions by Garner, and before that by Nicholson and by Lander. A comprehensive treatment of toxicology draws from the scientific disciplines of botany, chemistry, physiology, pathology and clinical medicine, and it might be thought impossible to produce at once a textbook for the student, a ready reference work for the practitioner, and an authoritative text for the research worker. This has been achieved, however.

In the past few decades there have been vast changes in the toxic hazards to which farm animals are exposed, for example, arsenic and copper compounds for the treatment of external and internal parasites have been superseded by chlorinated hydrocarbon and organo-phosphorus compounds. The range of organic pesticides used in agriculture is continually expanding, and it is to the authors' credit, therefore, that the third edition of this

volume is only some 10 per cent larger than the previous edition, although one new section has been added and others have been revised and enlarged.

The book is divided into eight sections. The first part consists of a general thesis on toxicology including mode of action of poisons, diagnosis and treatment, and the remaining seven sections constitute an exhaustive catalogue of toxic materials encountered by farm animals. Each poison is dealt with under the general headings of "Occurrence", "Absorption", "Toxic Dose", "Symptoms", "Post-Mortem Lesions", "Diagnosis" and "Treatment". The second part deals alphabetically with mineral or inorganic materials, and organic materials are treated in the third, fourth and fifth parts, under the headings of "Drugs", "Pesticides" and "Miscellaneous Compounds". One of the co-authors, Papworth, has rewritten the section on pesticides which contains very useful tables of chlorinated hydrocarbon and organo-phosphorus insecticides listing both chemical and proprietary names. These latter are also included in the index, which greatly facilitates location in the text.

The sixth part of the book, which lists the toxic hazards of the plant kingdom, has been enlarged to include plants from other continents as well as Europe, and has been rearranged so that families appear in alphabetical order. The seventh part, on the dangers from radioactive materials, has been rewritten and enlarged by Garner, and the next part is the new addition containing short accounts of venomous stings and bites and doping of racing animals.

In all the topics covered, the literature has been reviewed up to 1964 or 1965, and, with a few exceptions, all the important contributions have been included. Selection of materials has been judicious, as has been the omission of material of waning importance in modern agriculture.

As one of the very few works on veterinary toxicology in English this new edition will be welcomed by all who are concerned with diagnosis and treatment of poisoning in animals.

J. R. TODD

## FOOD MAY BE POISONOUS

### Toxicants Occurring Naturally in Foods

(A Monograph prepared by individual scientists of the Food Protection Committee.) (Publication No. 1354.) Pp. vii + 301 (Washington, D.C.: National Academy of Sciences, National Research Council, 1966.) \$6.00.

MUCH time, money and argument is now being spent (and rightly so) in several countries to produce legislation regulating the safe levels of use for the synthetic chemical substances which are added deliberately to food for various aesthetic and technological purposes (for example, flavours, colours and preservatives) or which may occur as contaminants in food as the result of manufacturing processes, packaging or the use of pesticides in agriculture. As this book clearly shows, however, natural foodstuffs contain a large number of chemicals which are not nutrients, many of which could be toxic to man and animals if the foods in which they occur were eaten in sufficient quantity. Poisoning as the result of eating natural foodstuffs may not be uncommon, for even the humble potato has caused many outbreaks of poisoning in man as a result of its content of the solanine alkaloids in certain circumstances. Those who would insist on eating natural foodstuffs without chemical fertilizers and pesticides and without chemical additives are, like most of us, not aware usually that poisonous substances or toxicants occur naturally in their food. As the various chapters in this book show, foods contain naturally such substances as goitrogens, oestrogens, carcinogens, lathyrogens, haemagglutinins, stimulants, depressants, allergens, pressor amines, antivitamins, antienzymes,

cholinesterase inhibitors and many other potentially toxic agents.

This book constitutes an interesting and useful introduction to the occurrence of and the problems arising from toxicants naturally present in food. It contains twenty-seven short chapters, some no more than four or five pages, by twenty-five contributors, and each chapter is supplemented by a useful bibliography. But, as pointed out in the discussion at the end by Dr J. M. Coon, who was largely responsible for organizing and managing the project, it was not feasible to attempt a comprehensive coverage of what is known in the field, and the selection of specific topics was somewhat arbitrary. Nevertheless, the book has succeeded admirably in directing attention to this field. About two-thirds of the book deals with organic compounds, many of which have pharmacological and toxicological properties. A small selection of the many substances mentioned will illustrate the scope: *l*-5-vinyl-2-thioxazolidone (goitrogen) in turnips, genistin (oestrogen) in soybeans, aflatoxin (carcinogen) in peanuts, methylazoxymethanol (carcinogen) in cycads,  $\beta$ -amino-propionitrile (lathrogen) in sweet peas, vicine (haemolytic agent in favism) in broad beans, tyramine (pressor amine) in cheese, histamine (pressor amine) in wine, solanine (cholinesterase inhibitor) in potatoes, cyanogenetic glycosides, physostigmine, gossypol, coumarin, safrol, allylthiocyanate, and fish poisons. There are also chapters on excess vitamins, indispensable amino-acids and essential minerals and a whole chapter on sodium chloride which could be toxic, in certain circumstances, to hypertensive patients. Oxalates, nitrates and nitrites, and natural radioactivity each have a chapter devoted to them.

The number of toxicants occurring naturally in food must be very large and there are many which undoubtedly remain to be discovered. It seems reasonable, therefore, that the same attention should be given to these substances as has been given to deliberate additives and pesticides, without, however, any diversion of attention from the latter. Some of these substances have, of course, received considerable attention as in the case of the aflatoxins. The question may be asked: if all these toxic substances do occur in the diet, why is it that their effects are not manifest in a large proportion of the population? Here and there in the various chapters of this book the possible answers to this question are to be found. The general impression one gets from reading this book is that, although the natural sources of man's food contain many chemical substances known to be toxic, most of them are not known to be harmful to normal healthy human beings consuming what has been established as a reasonable balanced diet prepared in time-honoured ways. It is clear that the normal detoxication mechanisms of the body are able to cope with these substances in these circumstances. Poisoning, however, does occur especially in communities living on limited diets, or on unusual foods, or on foods gathered during the toxic phase of growth of a plant or animal, or foods infected by toxic fungi. Poisoning may also occur in individuals in which the normal protective mechanisms are defective, such as the young, the sick or those with inborn errors in these mechanisms. Thus in Japan, 60 per cent to 70 per cent of all food poisoning is caused by fish or sea-food because marine organisms contribute 10 per cent of the total food supply. In some African peoples who use plantains as a major article of diet, the intake of serotonin may reach 100–200 mg/day and this has been suggested as a factor in the high incidence of endomyocardial fibrosis among Africans. The unripe ackee fruit of Jamaica can cause acute toxic hypoglycaemia because of its content of hypoglycin, and quail can be toxic in the spring when they return to Europe from Central Africa where they have eaten poisonous plants. The poisoning of the Hebrews by quail is referred to in the Old Testament (Numbers, 11).

Although it appears that there is no danger in normal circumstances from toxicants occurring naturally in foods, it is pointed out that problems could arise from the simultaneous presence of two groups of materials in our food, namely, the natural toxicants and the synthetic chemicals. Such problems have already arisen, as in the case of tyramine in cheese and certain antidepressive drugs, for foods rich in pressor amines (for example, certain cheeses, certain wines, for example chianti, pickled herrings, 'Marmite', broad beans) can produce hypertensive crises in patients undergoing treatment with monoamine oxidase inhibitors. The significance, however, of many of the known toxicants occurring naturally in food to the health of man through his consumption of foods containing them has yet to be determined.

The purpose of this book, as stated in the introduction, is to "present information, however ascertained, concerning the presence of naturally occurring toxic substances in man's food". This purpose has been achieved and the book will be read with profit by all interested in food toxicology.

R. T. WILLIAMS

## MONGOOSES OF THE WORLD

### Mongoose

*Their Natural History and Behaviour.* By H. E. Hinton and A. M. S. Dunn. Pp. vii + 144 + 16 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1967.) 42s. net.

THIS is a useful and well planned account of the natural history, in the widest sense, of the small carnivores forming the sub-family Herpestinae, widespread through Africa and southern Asia, in the family Viverridae. The co-authors have provided in a simple and easily readable form an up to date survey of all reliable knowledge of this distinct group of mammals.

The range of aspects is wide: separate chapters describe the always engrossing subject of relationships between mongoose and snake; oddities of mongoose behaviour; important ecological and economic effects of the introduction of mongooses to the Caribbean and Hawaiian islands; their history in ancient times with Oriental folklore; diseases and parasites; reproduction; and a final chapter reviews briefly the systematic arrangement as currently accepted and lists the existing genera and species, together with their distribution and native names. Some of the aspects of behaviour may not be familiar to the general reader, particularly the well authenticated habit of some species of breaking the shells of eggs, snails, mussels and even nuts by flinging these food items violently either downwards or backwards against a hard surface. Such behaviour is apparently innate in certain species.

The story of the relationship between mongoose and snake provides some fascinating reading. Most mongooses seem to possess a considerable degree of immunity to normal quantities of snake venom, although massive doses injected experimentally can be lethal. In nature it often happens that mongooses and poisonous snakes ignore each other, and most of the snake remains found in mongoose stomachs or droppings have proved to belong to harmless species. In the West Indies, where control of snakes was one of the purported objects of the introduction of mongooses, there appears to have been no appreciable change in snake populations. It is even reported that in Trinidad and some other islands the local boas find the mongooses a useful addition to their diet.

Much detailed information is given about other aspects of the wide introduction of the small Indian mongoose to the Caribbean and Hawaii. Undoubtedly the spread of these terrestrial, energetic, omnivorous hunters has

had a major effect on some forms of the endemic faunas, and although the part they play in controlling the rats which are often an important pest in sugar cane plantations (a part recently diminished to a considerable extent by the disastrous results, for the mongooses, of eating thallium-poisoned rat bodies) is recognized on some islands, on others control of the mongooses has been found necessary. A graphic illustration of the biological success of the mongoose in Trinidad is provided by the figures of mongooses on which bounty was paid in 1928, 1929 and 1930: 30,026, 32,650 and 21,231 respectively. A wry commentary on the snags inherent in any bounty scheme is that it has been found necessary on certain islands to make orders prohibiting the keeping of mongooses in captivity, as it was feared that they were being bred for the reward. One further significant aspect of the mongoose problem, particularly in the West Indies, is the discovery that these large populations constitute a major reservoir of canine rabies.

The final chapter, reviewing briefly the taxonomic list, is the only one marred by errors of omission or commission. For example, on page 109 it is stated that ten genera are now recognized, but in the lists which follow thirteen full genera are tabulated. On page 112, by way of introduction to the subject of local names, there is a reference to "the common mongoose of northern Nigeria", followed by a list of known native names for it. But the subsequent generic and specific lists make no further mention of this "common mongoose" nor of any of the names quoted for it. Again, under distribution, the information for several African species is notably incomplete; for example, the distribution of *Mungos gambianus* is given solely as Gambia, yet all the native names given for this species are clearly listed as Ghanaian, and in fact the range includes both Ghana and Sierra Leone. An inexplicable error is the inclusion of Sierra Leone and Ghana in the range of *Herpestes naso*, which has never been recorded west of south-eastern Nigeria.

Apart from these few technical errors in the final chapter, the book can be thoroughly recommended as a useful introduction to all aspects of mongoose biology and history; a very full bibliography completes the work, which is fully illustrated by both photographs and line drawings.

R. W. HAYMAN

## PRIMITIVE RELIGION

### Tikopia Ritual and Belief

By Raymond Firth. Pp. 374. (London: George Allen and Unwin, Ltd., 1967.) 63s.

THE island of Tikopia is as familiar to social anthropologists as the Isle of Dogs to a Cockney, for it is the subject of the most remarkable corpus of ethnography that the present generation of anthropologists has produced. The author of this book, Professor Raymond Firth, set an unsurpassed standard of field-work with his first study of the island thirty-eight years ago. Since then he has published other books deriving from his original visit and in 1952 he returned to the island to attack the problems of social change and was fortunate (from the theoretical point of view) to arrive at a time when a typhoon had wrecked the island and faced its inhabitants with a crisis that forced them to modify many of their traditional ways. He returned there again in 1966 when he appears to have been primarily concerned with the study of religion, a subject on which he gave us *The Work of the Gods on Tikopia*. This book is now re-issued as the first volume of a trilogy of which *Tikopia Ritual and Belief* forms the second. It collects together the various essays bordering the subject which have appeared during the past thirty-five years and adds a final commentary in the light of the author's most recent visit. Yet we

must await the promised volume, *Rank and Religion in Tikopia*, to assess Firth's contribution to the study of primitive religion. In the meantime it is very convenient to be offered these essays in a single volume. In spite of their diversity and the age of some, they represent a single point of view and even the oldest does not seem dated.

JULIAN PITT-RIVERS

## BEWARE OF THE MONKEY

### Zoonoses of Primates

The Epidemiology and Ecology of Simian Diseases in Relation to Man. By Richard Fiennes. (Manuals in Biology.) Pp. ix+190. (London: Weidenfeld and Nicolson, 1967.) 168s.

THIS book is the first volume in a series of manuals in biology intended for research workers and students and edited by Dr L. Harrison Matthews and Richard Carrington. The book's author is a veterinary surgeon who has been conducting for nearly twenty years field and laboratory studies of diseases of wild and domesticated animals in East Africa. Formerly head of the veterinary section of the faculty of agriculture in the University of Ghana, he is a graduate of the Universities of Cambridge and Edinburgh and has been pathologist to the Zoological Society of London since 1956. This book certainly reflects the author's wide experience of its subject, the scope of which he outlines in a foreword, which includes a valuable history and definition of the term zoonosis, which has been, as he explains, used in different senses by the authors he quotes.

In the first part of the book Fiennes discusses the affinities and classification of the primates and the complex ecology of their zoonoses, that is, diseases transmissible to man, a valuable discussion which makes it clear that the author is well aware of the intricate interactions of the many factors which govern the transmission of primate diseases to man. These include not only their vertical transmission from the arboreal habitats of the primates, but also their lateral transmission among terrestrial species, such as the rodents, which may be the means, with the help of vectors, such as mosquitoes, of infecting man, who may, once he is infected, be the starting point of serious epidemics among human populations. This maze is to some extent clarified by references to particular diseases, such as yellow fever and the numerous viruses which may be found in primates. This section, however, cannot be fully understood or appreciated unless the book itself is read. It should, indeed, be carefully read by everyone who is in any way closely associated with primates, not only for the sake of their own health, but also for the sake of the health of human populations to which they belong.

The second, third and fourth parts of the book give a disappointingly brief sketch of the various parasites of the primates, including the bacteria (among which are the bacillus of tuberculosis and enteric organisms which can cause serious diseases of man) and also the numerous viruses found in primates. Useful features are the tables which list the organisms concerned, and the list of viruses and their classification is especially useful. But many readers, especially perhaps students, will no doubt wish that more space had been given to all these organisms, so different from one another, and to their characteristics and to the structure of life histories of, at least, the protozoan and metazoan parasites, preferably with illustrations. The book ends with the author's summary and conclusions, which warn us, among other things, that man runs serious health risks when he associates closely with monkeys, although, in the author's opinion, the New World monkeys are probably less dangerous than the Old World species are.

The book is completed by a valuable and extensive bibliography of books and research papers and an author and subject index. As it is the first complete treatment of an important subject, it will be welcomed by doctors, veterinarians and everyone else concerned with the epidemiology of the diseases involved.

G. LAPAGE

## OBITUARIES

### Dr S. P. Wiltshire

THE Commonwealth Mycological Institute (formerly the Imperial Bureau of Mycology) at Kew has had two chief architects: Dr E. J. (later Sir Edwin) Butler, the first director, who laid a firm foundation, and Dr S. P. Wiltshire, who during his sixteen years as director designed much of the edifice. Wiltshire was largely responsible for the fine "new" building, opened in 1955, to house the library and the herbarium and, in addition, he initiated most of the projects by which information on plant disease, mycotic disorders of man and animals, and other aspects of mycology are currently disseminated by the Institute.

Samuel Paul Wiltshire, who died on May 13, 1967, was born on March 13, 1891, at Burnham-on-Sea, Somerset, and in 1914, after going to the University of Bristol and Emmanuel College, Cambridge, he joined the Long Ashton Research Station, to which he returned as mycologist in 1919 after a period of war work. There he investigated infection by the apple and pear scab fungi. In 1922 he was appointed by Dr Butler to the recently founded Imperial Bureau of Mycology, where he remained for the rest of his working life, becoming later assistant director and then director. In the same year he married Violet Gertrude, daughter of Dr Dukinfield Henry Scott.

The main function of the Bureau, which is still the basic function of the Institute, was to abstract the world literature on plant diseases and to publish the results in the monthly *Review of Applied Mycology*, which is now in its forty-sixth year. Wiltshire had the temperament to become a meticulous editor, and the increasing size of the literature and the increasing need for information led him to diversify the Institute's publications. He developed the regular publication of maps showing the distribution of plant diseases, supplemented the *Review of Applied Mycology* by a newsletter, and planned, but left his immediate successor to implement, a series of descriptions of pathogenic fungi and bacteria. He also initiated a second abstracting journal, the, now quarterly, *Review of Medical and Veterinary Mycology*, the *Index of Fungi* (in which new names proposed for genera and species of fungi are listed), and an annual (now half yearly) *Bibliography of Systematic Mycology*, listing taxonomic publications by titles. Finally, *Mycological Papers* (the main outlet for the taxonomic research carried out at the Institute but which also include other contributions, particularly from Commonwealth countries) and *Phytopathological Papers* were the results of his initiative.

Wiltshire was himself well known as a mycologist, and if his output was small it was of high quality, so that his papers on *Alternaria* (published in 1933) and *Stemphylium* (1938) are minor landmarks. He was president of the British Mycological Society for 1943.

Although the author of so many novelties, Wiltshire was very conservative in editorial matters, but his reluctance to make changes was basically a reluctance to jeopardize the high standards on which he always insisted. Reserved and of a retiring disposition, Wiltshire was seldom seen at scientific meetings and he travelled little. He was, however, a man of high principles and deeply

religious. The funeral service was held at the Ebenezer Baptist Chapel, Kew, which he had attended for thirty-nine years and served as a deacon for more than twenty.

G. C. AINSWORTH

### University News:

#### Dundee

DR A. R. MITCHELL, reader in the Department of Applied Mathematics in the University of St. Andrews, has been appointed to the third chair of mathematics (numerical analysis) in the proposed University of Dundee (Queen's College, Dundee, University of St. Andrews).

#### London

DR R. G. MASON, reader in geophysics at Imperial College, has been appointed to the chair of pure geophysics tenable at that College.

#### Reading

DR F. AYLWARD, at present director of the Fruit and Vegetable Preservation Research Association, Chipping Campden, has been appointed professor of food science. Dr Aylward will take up his position on the retirement of Professor E. L. Crossley at the end of the 1967-68 session, at which time the Department of Dairying will be renamed the Department of Food Science.

### Appointments

MR FRANK GREENAWAY has been promoted to the rank of keeper at the Science Museum.

### Meetings

COMPUTER Programming, August 7-25, Technical University of Denmark, near Copenhagen (H. J. Helms, Northern Europe University Computing Center, Technical University of Denmark, Lyngby).

INTERNATIONAL Lecture Meeting on the Combined Gas Chromatograph-Mass Spectrometer, August 9, at 7 p.m., School of Pharmacy, London (Dr P. R. Masek, LKB Instruments, Ltd., 232 Addington Road, South Croydon).

ERRATUM. In Fig. 1 of the communication entitled "Proton Current Flow in Mitochondrial Systems" by Peter Mitchell (*Nature*, 214, 1327; 1967) NADH Oxidase was wrongly printed as NADP Oxidase.

ERRATUM. In Fig. 1 of the paper "In vivo Effect of an Invasive Malignant Rat Tumour on Cartilage" by A. R. Poole and D. C. Williams (*Nature*, 214, 1342; 1967), the magnification should be  $\times c. 490$  and not  $c. 140$  as stated.

ERRATUM. In the communication "Methylation in vivo of Guanine in the Nucleic Acids of Rat Testes by Methyl Methane Sulphonate" by P. F. Swann (*Nature*, 214, 918; 1967), the third sentence in the legend to Fig. 2 should read:  $\bigcirc$  —  $\bigcirc$ ,  $E_1$  cm at 260 m $\mu$ ;  $\bullet$  - - -  $\bullet$ , radioactivity in c.p.m.

ERRATUM. Throughout the communication entitled "Adrenergic Effects of Chronic Administration of Neuroleptics" (*Nature*, 214, 1210; 1967) the following substitutions should be made: stereotypy for stereotype; neuroleptics for narcoleptics; phenothiazine for phenothiazone; butyrophenone for butyrophene; haloperitol for halopentol. In line 14 of the fourth paragraph on page 1211, adrenergic should read amphetamine.

CORRIGENDUM. With reference to the article "Synergistic Toxicity and Carcinogenicity of Freons and Piperonyl Butoxide" (*Nature*, 214, 526; 1967), the authors would like to make it clear that while some 'Freons' are common pesticide propellants, 'Freons 112' and '113', which were discussed in the article, are not used for this purpose, but as selective solvents. They would also like to point out that 'Freon' is a du Pont trademark and that the anaesthetic fluorocarbon halothane is not a 'Freon'.

# CORRESPONDENCE

## Applying Research

SIR,—Professor Temperley's interesting and stimulating letter (June 24, p. 1378) raises a number of points.

Although responsible for running a sponsored research institute, I would question his initial assumption that there should be a correlation between research expenditure and increase in GNP. Research increases knowledge or potential. Usually the knowledge is free for all and the people who provide the knowledge are not often in a position to exploit it commercially. In this respect research is in the same category as accountancy, which provides information but is not itself productive. It is perhaps unfortunate that so many accountants and business administrators consider research to be justified only by profitability, but fail to apply this criterion to other fact-finding activities, including their own. Although both research knowledge and accountant's information can help to increase production and profitability, other conditions have to be right, and a study of the accounts or a satisfactory outcome of research do not lead inevitably to financial gain. However, lack of knowledge of either type must result in eventual loss. We need knowledge to maintain as well as to increase production.

I cannot share Professor Temperley's concern about a Ph.D. being employed in devising production schedules. The Ph.D. degree is, after all, only an indication of a full education and there are few activities that are not the better for an educated mind. The idea that a Ph.D. demeans himself by going into production engineering is probably one reason why we, in this country, fail to use our best brains in increasing productivity. We would do better and be more likely to apply new knowledge effectively if we had university trained people as foremen, or even at the workbench, who would both welcome and understand innovation.

Another reason for failure to apply research in Britain is that most results which emerge from universities, Government laboratories, or research associations are made freely available. In some specific cases results may be exploited commercially through NRDC, but so far the costs of exploitation have tended to equate with or exceed the returns.

Finally, we have the tendency to restrict our scientific manpower by engaging technical staff to work only in specific fields and to maintain industrial establishments or teams of scientific workers in fields where there is no immediate commercial justification. When the icy winds of economic change are experienced, or when there is a change in the attitude of management, scientific personnel are thrown on the market, often when this is at its lowest ebb. This gives British industry the reputation of not being able to use scientific manpower and tempts scientists to seek work abroad.

The efficient use and exploitation of research can be best ensured by the establishment of multi-discipline organizations, in which both research and development can be carried out, with the results kept confidential until ready for exploitation, and where the staff can switch from one project to another without being hampered by the original terms of reference under which they were engaged.

Such an organization should contain experts on industrial management, market research, and commercial intelligence, as well as staff engaged in conventional science and technology. Probably even these business experts would be the better for a basic scientific or technological training, for the techniques involved are comparatively simple and capable of development and improvement by the application of scientific principles.

Such organizations as exist in Britain for sponsored research are hampered by being small in relation to similar

institutions in the US and by being unable to offer those other services by which contact and confidence are established between industry and the scientist. Recently both Arthur D. Little and Battelle have successfully extended their activities in this direction and include many British firms among their clients. Although there has been a very marked growth of management consulting organizations in this country, few of these are science based and one suspects that they recommend reduction of research expenditure or closure of research departments, rather than suggesting alternative lines of research likely to prove profitable. Thus they emphasize rather than reduce the rift between scientific research and industry.

By all means let us question the figures for British expenditure on research and development and their implications, as Professor Temperley suggests, but I, for one, am prepared to accept them as published and to be more concerned with how to remedy the situation. In my view this lies in the enlargement and extension of contract research facilities, coupled with industrial consultancy services in the same organization.

Yours, etc.,

E. A. G. LIDDIARD

*Director of Research,*  
Fulmer Research Institute Ltd.,  
Stoke Poges.

## What Place for Engineers?

SIR,—Professor Thring's ideas about an Academy of British Engineers are attractive. Certainly they have been given much thought within the Council of Engineering Institutions but, for the present, rejected for the reasons given in your leading article (June 17, p. 1175).

To expand on some of your comments, an important difference between the British engineering institutions and the American societies, affecting their relative standing in the community, is that the former are qualifying bodies while the latter are not. The former consequently enjoy a better status as learned societies and may be thought the more effective in promoting the art of engineering. The American federal body, the Engineers' Joint Council, has not had a workable constitution, being inherently unable to offer effective advice to Government. Very recently, its constitution has had a radical change. Whatever factors may be the cause of American industrial pre-eminence, the organization of their engineering profession does not seem to be one, and the need for a National Academy arose for reasons which are not relevant to conditions in Britain.

The CEI has an excellent relationship with the Royal Society. Sixty-three Fellows of the Royal Society are Chartered Engineers. This is not far short of the 10 per cent which had been the normal level of representation of the profession during the 19th and early 20th centuries, until the "Rutherford era" created a preponderance of pure scientists. The purpose for which the Royal Society was created by Charles II would seem to have been the furtherance of science for the betterment of industry by its application, and the engineer deserves a place in such a body. Remembering the difference in scale between the United States and Britain, there would seem every reason for the strength of engineering influence to be built up in the Royal Society rather than to create some new body whose relationship with the Council of Engineering Institutions would be difficult to define. In any case, scientists and engineers are very closely linked through collaboration in industry with the numbers employed of each not greatly different.

Yours, etc.,

J. R. G. FINCH

*Secretary,*  
Council of Engineering Institutions,  
London, S.W.1.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, July 10—Thursday, July 13

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS; INSTITUTION OF PRODUCTION ENGINEERS; and the INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at the University, Nottingham)—Joint Conference on "The Integration of Design and Production in the Electronics Industry".

## Tuesday, July 11

COUNCIL OF ENGINEERING INSTITUTIONS (at the Institution of Civil Engineers, 1-7 Great George Street, Westminster, London, S.W.1), at 10 a.m.—Conference on "The Structure of the C.E.I. Examination".

## Thursday, July 13—Friday, July 14

BIOCHEMICAL SOCIETY (at the University of Oxford)—473rd Meeting. Programme will include Dr J. B. Chappell: "The Transfer of Reducing Power between Cytoplasmic and Mitochondrial Nicotinamide Adenine Dinucleotides" (Colworth Medal Lecture); Symposium on "The Metabolic Roles of Citrate", and an Ordinary Meeting for the presentation of communications.

## Friday, July 14—Saturday, July 15

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMICAL METHODS GROUP (at Lincoln Hall, University of Nottingham)—Symposium on "Elemental Organic Microanalysis".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER/ASSISTANT LECTURER (preferably with a special interest in crystal structure analysis and in crystal chemistry and preferably some experience of teaching in crystallography) in CRYSTALLOGRAPHY—The Academic Registrar (LFG), University of Surrey, Battersea Park Road, London, S.W.11 (July 14).

LECTURER or ASSISTANT LECTURER in the DEPARTMENT OF CERAMICS, Houldsworth School of Applied Science—The Registrar and Secretary, The University, Leeds, 2 (July 14).

RESEARCH ASSISTANT (with an honours degree, preferably in physics, and willing to join a research group concerned with the image evaluation of optical and photographic systems) in the SCHOOL OF PHOTOGRAPHY, COLLEGE OF ENGINEERING AND SCIENCE—The Director of Education, The Polytechnic, Regent Street, London, W.1 (July 14).

SENIOR LECTURER or LECTURER (graduate in veterinary medicine, medicine or science and experience and/or an honours degree in physiology) in the DEPARTMENT OF VETERINARY PHYSIOLOGY—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (July 14).

ASSISTANT LECTURER in the DEPARTMENT OF CHEMICAL PATHOLOGY—The Registrar and Secretary, The University, Leeds, 2 (July 15).

LECTURER and an ASSISTANT LECTURER (graduates in pharmacology, pharmacy, physiology, biochemistry or medicine) in the DEPARTMENT OF PHARMACY—The Registrar, University of Strathclyde, George Street, Glasgow, C.1, quoting Ref. 48/67 (July 15).

LECTURER (preferably with research qualifications in solid state or superfluid theory) in THEORETICAL PHYSICS—The Secretary, University of St. Andrews, College Gate, St. Andrews, Fife, Scotland (July 15).

RESEARCH ASSISTANT in the DEPARTMENT OF BIOLOGICAL SCIENCES to collaborate in one of the following projects: biochemistry, general physiology or ultrastructure, genetics, microbiology—The Staff Officer, The University of Aston in Birmingham, Gosta Green, Birmingham, 4 (July 15).

SENIOR TECHNICIAN (A.I.M.L.T., A.I.A.T. or with similar qualifications, and experience in the care and handling of laboratory animals) in the PHARMACOLOGY DEPARTMENT—The Registrar, Brighton College of Technology, Moulsecomb, Brighton 7, Sussex (July 15).

S.R.C. RESEARCH STUDENT (with a good honours degree in physics, chemistry, engineering science or forestry) in TIMBER SCIENCE in the DEPARTMENT OF FORESTRY to work on an approved topic in the field of timber technology—The Professor of Forestry, University College of North Wales, Bangor, North Wales (July 15).

ASSISTANT LECTURERS (2) (with a special interest in economic geography) in GEOGRAPHY—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (July 17).

RESEARCH CURATOR in the DEPARTMENT OF GEOLOGY to assist with the preparation of exhibits and demonstrations, curating duties, and to spend half-time in research leading to a higher degree—The Assistant Bursar (Personnel), University of Reading, Reading, Berkshire (July 17).

RESEARCH STUDENTS in the DEPARTMENT OF CHEMICAL ENGINEERING—The Academic Registrar, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (July 17).

LECTURER (with a good honours degree in psychology, relevant industrial experience, and preferably some knowledge of air transport problems) in ENGINEERING PSYCHOLOGY—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (July 18).

TUTORS (2) in the DEPARTMENT OF GEOGRAPHY to assist with tutorial groups involving small groups of students and to provide assistance in practical map classes—The Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (July 18).

ASSISTANT EXPERIMENTAL OFFICER (with a degree or equivalent in botany, horticulture or related subject) to assist with ecological work on annual weeds of vegetable crops—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (July 21).

DIRECTOR OF COMPUTER SERVICES to be responsible for the organization and development of the central computing facility in the University which is at present equipped with an upgraded KDF 9 computer—The Assistant Registrar (S), University of Birmingham, P.O. Box 363, Birmingham, 15 (July 22).

GRADUATE PHYSICIST (preferably experienced or with a higher degree, but suitable new graduates considered) in the DEPARTMENT OF MEDICAL PHYSICS to join a team investigating electron spin resonance signals from animal tissues and develop new techniques—The Secretary, The University, Aberdeen, Scotland (July 22).

SENIOR LECTURER IN RHEUMATOLOGY—The Registrar, The University of Manchester, Manchester, 13, quoting Ref. 109/67 (July 22).

LECTURER (graduate in science or medicine with special qualifications and/or experience in virology) in VIROLOGY—The Secretary, Trinity College (University of Dublin), Dublin 2, Republic of Ireland (July 24).

LECTURER or ASSISTANT LECTURER in ELECTRON BEAM TECHNIQUES in the DEPARTMENT OF METALLURGY AND MATERIALS TECHNOLOGY, to take charge of a group concerned with electron microscopy, microprobe analysis, and related techniques—The Academic Registrar (LFG), University of Surrey, Battersea Park Road, London, S.W.11 (July 28).

SCIENTIFIC INFORMATION OFFICER (with a degree in agriculture or related subjects, a knowledge of German and flair for languages generally, and preferably with a reading knowledge of Japanese) to help production of two scientific journals of international repute—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, near Maidenhead, Berks (July 28).

SENIOR LECTURER (with special experience either in bacteriology, immunology or virology); and a LECTURER (graduate in science or medicine) in the DEPARTMENT OF BACTERIOLOGY—The Secretary, The University, Aberdeen, Scotland (July 29).

CHAIR OF BIOCHEMISTRY at the University of Auckland, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, July 31).

CHAIR OF STATISTICS; and CHAIR OF APPLIED MATHEMATICS—The Registrar, University College of Wales, Aberystwyth (July 31).

GRADUATE RESEARCH ASSISTANT (preferably with experience in geology, palaeontology and modern taxonomy) to work on a mesozoic palynology project for one to three years—The Secretary, Department of Geology, University of Cambridge, Downing Street, Cambridge (July 31).

LECTURER/ASSISTANT LECTURER (with experience in comparative neurophysiology and/or ultrastructural research) in the DEPARTMENT OF ZOOLOGY AND COMPARATIVE PHYSIOLOGY—The Assistant Registrar (S), University of Birmingham, P.O. Box 363, Birmingham, 15 (July 31).

LECTURER (preferably medically qualified or in possession of a Ph.D. degree with a basic training in pharmacology) in the DEPARTMENT OF PHARMACOLOGY—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (July 31).

READERS (2) in MECHANICAL ENGINEERING—The Academic Registrar (LFG), University of Surrey, Battersea Park Road, London, S.W.11 (July 31).

RESEARCH DEMONSTRATORS (2) (with a good honours degree in chemical engineering or, exceptionally, in other branches of engineering, in chemistry or in applied physics) in the DEPARTMENT OF CHEMICAL ENGINEERING—The Academic Registrar, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (July 31).

SENIOR LECTURER or LECTURER in SOCIAL ANTHROPOLOGY at the University of Auckland, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, July 31).

ASSISTANT LECTURER or LECTURER in the DEPARTMENT OF INORGANIC, PHYSICAL AND INDUSTRIAL CHEMISTRY—The Registrar, The University, Liverpool, quoting Ref. RV/62/N (August 1).

UNIVERSITY LECTURER (preferably with special interests in one or more of the following: theoretical geochemistry, crystal chemistry, sedimentary geochemistry) in GEOCHEMISTRY in the DEPARTMENT OF GEOLOGY AND MINERALOGY—The Secretary of Faculties, University Registry, Oxford (August 1).

LECTURER/ASSISTANT LECTURER (with a background in the physical sciences and preferably bilingual in Malay and English) in SCIENCE METHOD; a LECTURER/ASSISTANT LECTURER (preferably bilingual in Malay and English) in GEOGRAPHY METHOD; and a LECTURER/ASSISTANT LECTURER in EDUCATIONAL PSYCHOLOGY at the University of Malaya—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Kuala Lumpur and London) (August 4).

SENIOR LECTURER or LECTURER (Clinical) in PSYCHIATRY at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, August 4).

SENIOR LECTURER or LECTURER in the DEPARTMENT OF PATHOLOGY, Monash University—The Academic Registrar, Monash University, Wellington Road, Clayton, Victoria, Australia; or The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia, August 4).

READER in PHARMACEUTICS at the School of Pharmacy—The Academic Registrar, University of London, Senate House, London, W.C.1 (August 7).

LECTURER in MATHEMATICS at the University of Natal, Pietermaritzburg, South Africa—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, August 15).

GENETICIST (with an interest in the cytology of interspecific crosses); and an AGRONOMIST to work mainly on flowering control, and on agronomic characters in selection—The Secretary, West Indies Central Sugar Cane Breeding Station, Groves, St. George, Barbados (August 30).

PROFESSOR OF MATERIALS TECHNOLOGY in the DEPARTMENT OF METALLURGY AND MATERIALS TECHNOLOGY—The Academic Registrar (LFG), University of Surrey, Battersea Park Road, London, S.W.11 (August 31).

PROFESSOR OF CLINICAL SCIENCE AND DIRECTOR OF THE WELLCOME MEDICAL RESEARCH INSTITUTE, University of Otago, Dunedin, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, September 15).

BIOCHEMICAL RESEARCH ASSISTANT (Basic Grade) for studies of human muscle metabolism in health and disease (post suitable for recent graduate) at the Midland Centre for Neurosurgery and Neurology, Holly Lane, Smethwick—The Group Secretary, West Bromwich and District General Hospital, Edward Street, West Bromwich.

GRADUATE FOR BIOLOGICAL RESEARCH in the DEPARTMENT OF DERMATOLOGY—Dr I. Sarkany, The Royal Free Hospital, Gray's Inn Road, London, W.C.1.

JUNIOR LECTURER in CHEMISTRY—The Registrar, Victoria University of Wellington, P.O. Box 196, Wellington, New Zealand.

LECTURER (with a first- or second-class honours degree or equivalent, a thorough grounding in electrical engineering with a special interest in the field of electrical machines and/or electrical materials and in their applications and preferably experience in teaching, research or industry) in ELECTRICAL ENGINEERING—The Registrar, Royal Military College of Science, Shrivenham, Swindon, Wiltshire.

LECTURER (with an interest and experience in educational psychology with particular reference to learning theory and/or the methodology of teaching) in EDUCATION at the University of Malawi—The Inter-University Council, 33 Bedford Place, London, W.C.1.

**PHYSIOLOGIST or ZOOLOGIST (graduate)** for research on emotional behaviour in the rat—Dr. J. A. Gray, Institute of Experimental Psychology, The University, 1 South Parks Road, Oxford.

**POSTGRADUATE PHYSIOLOGY STUDENT** for research into ion transport across membranes—Prof. J. Anderson, Department of Medicine, King's College Hospital Medical School, London, S.E.5.

**RESEARCH ASSISTANT** in the DEPARTMENT OF PHYSICS to work with a research group supported by the Science Research Council investigating the properties of metals at high rates of loading using pulse propagation methods—Prof. John Raffle, Loughborough University of Technology, Loughborough, Leicestershire.

**TECHNICIAN** to operate and maintain analytical ultracentrifuges and other specialized instruments for research in molecular biology—The Administrative Officer (Ref. EGR), Biophysics Research Unit, Medical Research Council, 26-29 Drury Lane, London, W.C.2.

**YOUNG GRADUATE or TECHNICIAN** (preferably with experience with an autoanalyser for amino acid analysis) for the BIOCHEMISTRY RESEARCH LABORATORY—The Establishment Officer, University College London, Gower Street, London, W.C.1, quoting Ref. BC/9.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

The Water Research Association. Twelfth Annual Report for the year ended December 31st, 1966. Pp. 48. (Medmenham. Marlow: The Water Research Association, 1967.) [155]

University of Strathclyde. Annual Report, 1965/66. Pp. 76. (Glasgow: University of Strathclyde, 1967.) [155]

University of Cambridge. Report of the Head of the Department of Engineering for the year 1965-66. Pp. 16. (Cambridge: The University, 1967.) [155]

The Institution of Gas Engineers. Communication 737: Applications and Development of the Catalytic Rich Gas Process. Part 1: Research at Solihull. By H. S. Davies and K. J. Humphries. Part 2: Commercial Plants. By Dr. D. Hebdon and Dr. D. A. Percy. Pp. 19. Communication 738: Recent Developments in Water Usage and Effluent Disposal in the Gas Industry. By T. A. Dick. Pp. 11. Communication 739: Natural Gas: Some Comments on the Change-over to Natural Gas and on the Development of Sales in a Dutch Town. By Ir. G. H. Hellendoorn. Pp. 10. ## HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

\*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire ..... £14.0.0 each  
United States of America ..... (by air freight) ..... \$44 each  
Canada ..... (by air freight) ..... \$47.80 each  
Elsewhere overseas by surface mail ..... £13.15.0 each

(Charge for delivery by air mail on application)

\*Shorter periods *pro rata*. (Minimum three months.)

### MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

12 MONTHS (52 issues and 4 indexes)

Number of Copies	G.B. & Eire	U.S.A.	Canada	Elsewhere (surface mail)
	Each	Each	Each	Each
3-5	£13.10.0	\$42	\$46.00	£13.10.0
6-11	£12.15.0	\$40	\$43.60	£12.15.0
12 or more	£12.0.0	\$38	\$41.70	£12.0.0

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

### Editorial and Publishing Offices of "NATURE"

MACMILLAN (JOURNALS) LIMITED

4 LITTLE ESSEX STREET, LONDON, W.C.2.

Telephone Number: 01-836 6633. Telegrams: Phusis London W.C.2.

### Subscription Department

MACMILLAN (JOURNALS) LIMITED

BRUNEL ROAD, BASINGSTOKE, HANTS

Telephone Number: Basingstoke 5431

Annual subscription: United Kingdom and Eire £14, U.S.A. \$44 (air freight), Canada \$47.80 (air freight), all other countries £13 15s. (surface mail), payable in advance.

Advertisements only should be addressed to

## IS THE AEA NECESSARY?

NOBODY needs a clairvoyant to persuade himself that the weeks ahead will be critical for the UK Atomic Energy Authority. The doubts which have hung over the AEA for several years, and which have been explicit for at least two, are plainly about to be resolved. There are a number of signs of that. Although Sir William Penney is about to retire as chairman of the authority in only a few weeks, his successor has not yet been appointed. Then the Select Committee on Science and Technology of the House of Commons has uncovered—by no particular cleverness on its own account—a great deal of confusion and even anger about the way in which the commercial exploitation of nuclear reactors is being carried out (see *Nature*, this issue, page 235). There is talk, some of it wild, about the dismemberment of the authority, and it seems as if the committee appointed to consider the future of the thermonuclear fusion laboratory at Culham has raised the possibility—unacceptable to the board of the authority as a whole—that the laboratory might with advantage be shut down altogether. From time to time, ministers in the House of Commons promise statements on the future of this or that part of the authority's activity. The departure of Sir John Cockcroft from the authority at the end of this month will be a sad occasion, and a nostalgic reminder that things will never be the same again.

The reasons why the authority has been transformed from a kind of national hero in the mid-fifties into a subject for dispirited speculation are also easy to determine. In part, of course, the AEA has worked itself out of a job, at least where research and development are concerned. A decade ago there were half a dozen types of civilian reactors on the stocks, ranging from thermal gas cooled reactors to marine propulsion units and fast reactor prototypes. It was entirely sensible that this programme should engage the efforts of a large engineering force based in Lancashire and a large laboratory engaged on basic research at Harwell. For a time, indeed, there was even some sense in the AEA's argument in favour of a reactor testing station at Winfrith Heath in Dorset. And a decade ago, of course, there was a sufficiently vigorous military programme to occupy the efforts of the large laboratory at Aldermaston. In one way or another, the steam has now gone out of most of these activities. In defence, economy has become the watchword, and there is not much for the laboratory at Aldermaston to do. On the civilian side, it is now clear that there is no real need to develop types of thermal neutron reactors other than those now coming into service with the Central Electricity Generating Board. Fast reactors have a future,

and may even begin to make a commercial contribution a decade hence, but development work on them was costing only £12 million last year, and is likely to cost only £150–£200 million between now and 1975, when fast reactors may become commercial. In the circumstances it is not surprising that the laboratory at Harwell, like that at Aldermaston, looks a little like a whale left stranded by a retreating tide. What is going to happen?

The first thing to say is that in spite of all the uncertainties, the AEA has a splendid record for getting things done. It was able to function with speed and panache in the mid-fifties, when the rest of British industry was still too inclined to feel sorry for itself. That is something to be pleased about. But the authority, like the government to which it is responsible, has been unreasonably slow to appreciate the need of change. In the past few years it has oscillated between defensiveness and a pretence that nothing has changed. Much of the trouble can be traced back to the way in which the AEA evolved out of the old atomic energy group at the Ministry of Supply. From the beginning, it was an immensely powerful organization. In its relationships with academics, the authority was rightly respected. In its dealings with industry, it was able at the beginning to act paternal or, worse, avuncular. The authority's unkindest critics may say that it was endowed with all the arrogance but none of the inhibitions of the Civil Service from which it sprang. Whatever may be the most accurate form of words, the truth is that the AEA's inclination to do all its research and development itself is one of the reasons why it is now so vulnerable to changing circumstances—and, in passing, one of the reasons why the nuclear power industry in Britain finds independence uncomfortable. There is a powerful echo here of the declaration some months ago by Professor P. M. S. Blackett (see *Nature*, 213, 755; 1967) that successive British governments may have been mistaken in choosing to concentrate research and development in publicly operated laboratories.

Muck-raking by itself will not unfortunately suggest what should be done, although a recognition of past mistakes may help to avoid a repetition. The first need is to be clear why reorganization has now become essential. In the first place, there is a need of structural reorganization of the relationships between the AEA, the CEBG and the industrial consortia in the nuclear power business, chiefly so as to ensure a more effective exploitation of nuclear power domestically and in exports. This is the problem with which the Select Committee has been principally concerned, and it is improbable that the Minister of Technology will have

the cheek to announce important decisions before the committee produces its report some time after the summer holidays. But it is also important to make sure that the fullest use is being made of the resources at the disposal of the AEA, and from this point of view it is more important that Harwell employs 6,000 of the most skilled people in the United Kingdom than that it costs £15 million or so each year to operate. Obviously it is impossible to guess at what will actually happen to this and the other laboratories in the AEA, for even if the facts were all accessible, there can be no assurance that the Minister of Technology will be guided by pure reason and nothing else. Yet it is possible to see which way the wind is blowing or should blow.

Some things are simple. The Culham laboratory, principally concerned with long-term plasma research, will obviously be exceedingly uncomfortable if it continues within the AEA, at least as long as the Ministry of Technology is preaching the virtues of quick results. But it would obviously be unwise to throw away the investment of the past decade in thermonuclear fusion, especially when the Culham laboratory has acquired a distinguished international reputation. In the circumstances, the best place for it would be within the Science Research Council, where it would be insulated from a great many of the pressures which at present afflict it, and where it could also serve more effectively to fertilize research at the universities.

But on what scale? To people at Culham, this may seem the most important question, and there has recently been some optimism because the budget of the US Atomic Energy Commission for the current fiscal year includes an extra 15 per cent for research in fusion, and because the US Atomic Energy Commission has smugly predicted that it will need an extra 15 per cent in each of the next five years. It is important therefore that the AEC won its extra funds (which amount to rather less than \$3.5 million for 1968) by emphasizing the way in which expenditure at places such as Culham has grown in recent years, and that in any case the AEC may find itself in a similar plight to that of the UK authority long before five years have gone. In practice, there is a case for letting the Culham budget find its own level within the competitive atmosphere of the Science Research Council. The chances are that the budget would settle down at less than what it is at present, but that shrinkage would be slow. The Culham laboratory should also in future be restrained from over-ambitious ventures outside fusion proper. The way in which the laboratory has hogged the centre of the stage in the construction of the ESRO satellite has hindered rather than helped the cause of European collaboration.

The problem of Aldermaston is next in order of difficulty. The laboratory is larger, with 4,000 people on the books. It stands apart from the rest of what the AEA is up to, chiefly because of its inevitable pre-occupations with secrecy. For good management alone, the Aldermaston laboratory would most comfortably be placed alongside the other laboratories

preoccupied with defence technology—Aldermaston (aircraft) and Malvern (radio) beneath the wing of the Ministry of Defence. This implies that Aldermaston, too, is at home within the Ministry of Technology, and that its people not at present fully occupied in the industry have a better chance to move to useful jobs, or at least to be fitted out for a new career in modern industry.

Harwell is a more difficult problem, partly because the laboratory does actively support reactor development and partly because it has for two years been pursuing—with the blessing and the encouragement of the Ministry of Technology—the most active programme of diversification in any government laboratory. Unfortunately it remains a fact that if Harwell did not exist, nobody would dream in present circumstances of inventing it. Direct support for reactor development, which occupies perhaps a fifth of what the laboratory does, could if necessary be done elsewhere. The programme of diversification, concerned as it is with matters as different as the development of preparative centrifuges and the desalting of water, may be too much of a hotchpotch to accommodate within one organization and is, in any case, too much detached from industry. Historically, of course, diversification derives from the palmy days in which the Labour Party, not then a government, cherished oversimple notions of strategy for technology which have now been replaced by good sense except in connexion with public day-dreaming about what is called the European Technological Community. In other words, if the Minister of Technology is tender-hearted and suggestible, he will give Harwell a year or so to see whether diversification really works. Nobody would complain if he took the only other acceptable course, and lumped it with Aldermaston into the Ministry of Technology.

But is it permissible to treat people, especially talented people, as if they were parcels of equipment? This question may have helped to hypnotize the Ministry of Technology in the past few years. In a sense, the government's reputation as an employer of scientific labour is at stake. Although the AEA has been an autonomous public corporation for more than a decade, there is no doubt that the government as such is ultimately responsible for broad policy decisions. If the laboratories at Aldermaston and Harwell were now unthinkingly transferred back to the Civil Service, the people most concerned would be more dispirited than ever.

Everybody knows that if creative people engaged in applied science have no realistic objectives at which to aim, they tend to go to seed. Uncertainty has persisted so long at Aldermaston and Harwell—and at other government laboratories as well—that it has become a considerable scandal. What the Ministry of Technology must first do is to make a realistic decision about which parts of these two laboratories would be most usefully and creatively employed within the Civil Service. Then it must squarely face the need to find outlets elsewhere for the talents now frustrated

at the two laboratories. It will not be enough to sit back and wait for the problem to solve itself—the principal result of doing nothing will be to increase the rate of emigration. In part, the Ministry of Technology must set itself up as a superior labour exchange, able to find jobs with tempting salaries in industry and elsewhere for people who are the victims of their own success. Often it could help with training programmes, and it is ironical that the computer people should be crying out for systems analysts at a time when there are plenty of able people eating their hearts out at Harwell and Aldermaston. Above all, the ministry should recognize that the characteristic meanness of the public service towards those who work for it is one of the most serious impediments to change.

There remains the problem of how the development of new reactor systems should be managed in the years ahead. Unfortunately the Select Committee was so preoccupied with trying to decide which kind of reactor system is best that it did not examine as closely as it should have done the several alternative patterns of organization which are possible. At one extreme there is something very like the present arrangements under which the AEA is largely responsible for new developments and even for the construction of sizable prototypes, in which the three consortia are kept closely informed and given opportunities to tender for whatever orders there may be, in which the CEBG acts as the final arbiter of what kinds of power reactors should eventually be incorporated into the British programme, and in which the AEA and the three consortia do their best to work hand in glove in exploring markets abroad. Most of the defects of these arrangements stem from the way in which the AEA has been able to dominate its industrial partners technically and financially, with the result that the consortia lack experience, skill and confidence. This is why some people say that it would be better if the AEA concentrated on the processing of fuel and reactor materials, the ownership and operation of central facilities such as testing reactors, long-term planning and the allocation of funds for actual developments to those industrial companies best able to make use of them. This is a pattern very much like that in the United States—and it is perhaps important that the AEA is constantly having to complain that even in the United States industrial companies are unwilling to invest much of their own money in new kinds of reactors. Fortunately most of the interested parties seem to be agreed that there should be less wasteful duplication on reactor design and development, which implies some centralized authority spending public money, but with much stronger links with industry. The need is already recognized where experts are concerned, although not much has been done so far. It would be entirely in character with the ministry's recent pronouncements if it now looked to the Industrial Reconstruction Corporation for a more comprehensive solution.

With all this preoccupation with reorganization it should not necessarily be accepted that the present

programme of reactor development should, like the more distantly oriented research programme, be dispersed. Indeed, it is entirely possible that the development of fast reactors should not be restricted to the liquid sodium type. A year or so from now, the AEA or whichever other authority is in charge may easily wish to explore the potential benefits of gas cooled fast reactors, for example. Anything is possible and one object of the reorganization now in prospect should be to tie the development of new types of reactors much more simply than at present to straightforward commercial objectives. If, for example, it seems that a development on which work is well advanced is unlikely to be profitable, work should be stopped and nobody should cry scandal. (The Dragon high temperature gas cooled reactor could easily become one case in point.) But on the other hand there should be every encouragement for the responsible authority to back two alternative horses or even more if it seems that one of them is bound to win a substantial prize but if it is also impossible in advance to predict which will be the winner. All this is entirely consistent with the view that what is coming to an end is not nuclear power as such, but the need of a greater diversity of new developments.

In the real world, of course, nothing is simple, and in this sense there will be no reason to complain if the Ministry of Technology produces a scheme of reorganization which is not as tidy as it might be. The problem of how best to organize the relationship between the nuclear power industry and the rest of the British industrial economy is also unlikely to be settled in one swoop, fell or otherwise, so that it would make sense to have one scheme now and another three or four years hence. To say this is not, however, to imply that it will be in order for the Ministry of Technology to dodge the issues which have now been raised by circumstances, and to let uncertainty persist. If the AEA may in part have worked itself out of a job, it remains one of the most competent and formidable technical organizations in Britain. The problem with which the ministry must grapple is how to redeploy some of these resources. To do so, it will have to define—for others, not just itself—a coherent picture of how these invaluable resources might otherwise be occupied. Its vision of the future must take full account of how the people most directly concerned have wives, families and mortgages on houses in frequently outlandish places. Successful reorganization could bring great benefits and make everybody feel happier. Failure could be disastrous. And this, in a curious way, is as it should be. For the past two years the British Government has been telling everybody what wonders it would accomplish if only it had a real chance to redeploy technical resources in industry. All the time there has been a splendid opportunity waiting on its own doorstep. Not merely the future of this important sector of scientific industry but its own reputation as well will be determined by its decisions in the weeks ahead. Will it be brash, or cowardly, or somewhere in between?

## NEWS AND VIEWS

### No Future for Collaboration?

THE failure of Anglo-French collaboration on a variable-geometry aircraft has been so long discounted that when it finally happened the twitching of upper lips in Whitehall was barely perceptible. The agreement, which is a polite way of describing the working truce which Mr Denis Healey and M Pierre Messmer had reached, seems to have been a model of how not to collaborate. For a start, both sides had a totally different conception of what the aircraft might be—the French wanted an interceptor to operate primarily within Europe while the British requirement was for an aircraft with much more general functions. It was to be a strike aircraft, an interceptor, a reconnaissance plane. At one stroke it would replace Canberras, Phantoms, Lightnings, conceivably even the F 111 K. At the same time there were hopes that the German Air Force would want it as a replacement for the Starfighter. Overburdened by its roles, the plane simply lay down and died; although the coup de grace was wielded by M Messmer on grounds of cost, there is little doubt that ultimately there would have been technical reasons for opting out. One of these was the development by Dassault of the Mirage 3G, a single-engined aircraft which may well fill the role the French see for the VG aircraft.

The cancellation must give the Ministry of Defence furiously to think. The 1966 Defence White Paper described the AFVG as "operationally and industrially the core of our long-term aircraft programme". For delivery in 1974, each plane was to have cost about £1.5 million. This is to be compared with the cost of the F 111 K which is being bought from the US; a ceiling price of £2.1 million for each aircraft has been agreed, but may well only cover the first fifty to be bought. After the modifications and additions which the RAF insist on, the planes will each cost £2.5 million, and will as bombers be able to carry about twice the load designated for the AFVG.

The ministers responsible, Mr John Stonehouse at Technology, and Mr Healey at Defence, are now said to be looking for alternative partners for the VG project. This may be hard indeed, because of Britain's peculiar position. With commitments in the Far East, and a defence policy which makes an uneasy compromise between the high sophistication of the US and the USSR and the down to earth practicality of a nation like Sweden, Britain's requirements are unique. All the arguments against collaboration with France apply in equal measure to collaboration with Germany, Holland, or Italy. To pretend otherwise is a delusion.

As if to rub salt in the wound (though it is doubtful if any such deviousness entered the question) the USSR last week demonstrated its own swing wing aircraft. There were apparently two of them on show, one an interceptor-fighter, the other a strike aircraft. Clearly the USSR believes that the two roles call for two aircraft. Also shown was a vertical take-off aircraft. In appearance the Russian planes were somewhat similar to the F 111.

What now is the future of Anglo-French co-operation? There are currently five projects either in prospect or in existence: Concord, the Jaguar fighter, the proposed airbus, the Martel guided missile, and a joint agreement on helicopters. Two helicopters are to be produced, the French SA 340 and the British WG 13. In the interest of mollifying the French, much of the design leadership has been ceded to them, and Mr Stonehouse (or Mr Healey) may now feel that without the VG the helicopter agreement looks rather one-sided. Attempts to adjust it in Britain's favour will doubtless be made, but the result may very well be that the helicopters will follow the VG into limbo.

### Computers Hang Fire

THE latest figures produced by the Ministry of Technology about the British computer market make cheerless reading. Between the first quarter of 1966 and the first quarter of 1967, exports of computers manufactured in Britain were substantially unchanged, and amounted to £8.3 million in the quarter. During the same period, the delivery of British computing equipment to the domestic market actually declined, from £21 million in 1966 to £18 million in 1967, largely because of a reduction of the value of computer equipment manufactured in Britain from components imported from elsewhere.

This sad state of affairs is reflected, in part at least, in the figures provided by the ministry for computers now on order from British manufacturers. Between the first quarter of 1966 and the first quarter of 1967, there was no important change in the value of export orders, which declined slightly from £28 million to £27 million. Domestic orders for computing equipment increased substantially, however, from £88 million to £133 million. There will no doubt be wry speculation in some quarters that in spite of the British Government's economic restrictions in the past year, such growth as there has been consists of domestic investment and not export. The ministry points out that there are great uncertainties in these comparisons, chiefly because the figures for 1966 do not strictly compare with those for the current year, but even so it is compelled to acknowledge that there is "cause for anxiety". The ministry is also unhappy that £55 million of the orders for the domestic market are for what is called "factored equipment".

One by-product of this statistical exercise is that the ministry now has available figures showing how many people are employed in various stages of computer development and manufacture. Altogether some 37,300 skilled people are employed in the computer industry, 11 per cent of them on design and development, 41 per cent on manufacture and 13 per cent on sales.

### Whatever Happens to Physicists?

MORE information about the distribution of PhD physicists in Britain has now been gleaned by Professor J. C. Willmott, Director of the Physical Laboratories at the University of Manchester. The survey which Professor Willmott has been carrying out was mentioned briefly in *Nature* (214, 443; 1967) and has recently been published in the *Bulletin* of the Institute of Physics and the Physical Society.

Professor Willmott's survey follows one made in 1961 by Professor A. W. Merrison, which showed that of physicists with doctorates, 26 per cent entered government service, 22 per cent went into industry, 27 per cent stayed in the universities, and 18 per cent went abroad. After some prodding, Professor Willmott persuaded 26 universities to reply to a similar questionnaire in October 1966, and produced the results shown in Table 1.

	First employment		Present employment	
	No.	Per cent	No.	Per cent
Government service	83	11.2	79	10.8
Industry	95	12.9	79	10.8
Universities	308	41.8	302	41.2
Technical colleges	18	2.4	23	3.1
Teaching	18	2.4	16	2.2
Abroad	217	29.3	234	31.9
Total	739	100	733	100

The table shows first that a substantial number of physicists have stayed in universities, a piece of conventional wisdom these days, and the fact that government laboratories are now taking fewer than in the past because of the more modest scale of their activities. What alarms Professor Willmott is the sharp increase in the numbers going abroad and the decline in the numbers going into industry. Not only have the numbers declined since 1961, but there is an actual decline between first and present employment, from 12.9 to 10.8 per cent. Professor Willmott fears that physicists take one look at industry and then turn tail and rush back to the universities as fast as they can. (It is fair to point out that the Swann report did not paint such a dismal picture—it suggested that the proportion going into industry was nearer 20 per cent.)

These figures are not, perhaps, surprising, but add to the volume of evidence which is now accumulating about the use of qualified manpower in Britain. But Professor Willmott has gone further in seeing differences between different branches of physics. While the sample was smaller, and the division between different branches of the subject sometimes blurred, the figures are revealing. Of solid state physicists, for example, 19.7 per cent take their first job in industry, while only 5.7 per cent of nuclear and elementary particle physicists do so, and only 2.6 per cent of theoretical physicists. In each case the numbers show a decline between first and present employment. The numbers staying in universities—36.7 per cent of the solid state physicists, 41 per cent of the particle physicists, and 55.3 per cent of the theorists—are almost constant between first and present employment. It is difficult to draw any conclusions from this, except the obvious one that investment in solid state research in universities is more effective industrially than investment in other forms of physics: it is still a poor investment, though.

## In and Out of Space

THIS is likely to have been a week of great importance for space research in Europe. Although Europa I, the sixth in the programme of rocket launchings being organized by ELDO from Woomera in Australia, failed to leave the ground on Monday, July 10, the chances are brighter than they have been for at least a year that there will now be some sensible marriage

of the collaborative programmes in Europe for rocket development and space research. Certainly the proposal that ELDO (European Launcher Development Organization) and ESRO (European Space Research Organization) should be merged was one of those discussed at a meeting of government delegates at Rome this week. It remains to be seen whether member nations will be prepared to sink their separate ambitions in a programme which would develop a launching vehicle and then provide something for it to do. Another of the questions to be decided is how best to provide machinery for a continuing review of policies within ELDO and ESRO, married or single. Nobody wants to repeat the unseemly public squabbles which nearly brought ELDO to an end a year ago.

European space research will also be helped along a little bit by the holding in London between July 17 and 29 of the annual ICSY meetings of the IQSY (International Year of the Quiet Sun) and of COSPAR. It is thought that the IQSY meeting will be one of the first opportunities to survey the work of that period of collaborative activity.

## Good Health

THERE has been a curious contrast in the past week between the annual report of the Ministry of Health (HMSO, 19s.), with its cosy account of how the National Health Service in Britain is developing, and some of the things which doctors have been saying at the annual conference of the British Medical Association at Bristol. Innocent observers would be hard pressed to know whether the service is making progress towards some comfortable millennium or, alternatively, will have collapsed before the year is out.

The Ministry of Health acknowledges that the National Health Service "continued to be the subject of much public discussion", and regrets that "some of this has sought to give the impression that the year has been one of disappointment and failure". The truth, says the ministry, is that there has been "a striking measure of success". In practice, £75 million is to be spent on hospitals in the current financial year, which is said to be 63 per cent more than the rate of spending (in real terms) before the war; but in any case the ministry plans to spend £100 million a year in the next decade on new hospital building. The report unfortunately does not say whether the ministry considers an increase of 63 per cent in the rate of hospital renewals is enough to cover the increased sophistication of hospital treatment since before the war.

On the productivity of hospitals, the ministry points out that the number of patients being treated in hospitals has increased by 30 per cent in the past decade even though the population as a whole has only increased by 7.6 per cent. There are also increases in the numbers of patients treated in each available hospital bed—in 1956 the average was 16.6 patients per bed per year and in 1966 it had increased to 22.6. The ministry is also able to claim that medical staffs in hospitals have increased numerically by 60 per cent since 1949, but the report admits that still more doctors are necessary if the hospitals are to function efficiently. It points out that, in the past two or three years, there has been a vigorous growth of health and welfare services provided by local authorities. One

reason for this is that health centres housing both general practitioners and local authority services are springing up in many places. The ministry seems to be convinced that this development will take an increasing proportion of the health service budget in the decade ahead.

The report also gives details of the total size of the budget and how it is divided among the competing branches of the service. In 1965/66 the Health Service cost £1,241 million, a figure expected to rise in 1966/67 to £1,367 million. Hospitals account for about half the total budget (£687 million on current expenditure and £81 million on capital expenditure in 1966/67). Drugs will cost £142 million this year, local health services £127 million, general medical services £98 million, and dental services £70 million. Income from patients in 1966/67 is expected to be about £19 million. Faced with figures like these, it is easy to understand the problems which the minister, Mr Kenneth Robinson, must face when he asks the Treasury for more. It is also easy to see why the doctors were driven to suggest in Bristol that more of the cost of the service should be carried by the patients. Ignoring the most extreme attitudes, sometimes expressed in the claim that the relationship between patients and doctors would somehow be magically transformed for the better when money is allowed to change hands, there may nevertheless be a case for saying that the Health Service will have to become more selective.

## Boom in Physics

THE Institute of Physics and the Physical Society (which is the name of a single learned society based in London) is evidently pleased with its own growth in the past year and the prospects for extending its activities into Europe in the immediate future. In the annual report of the council of the Institute of Physics and the Physical Society presented to the annual general meeting on July 4, membership is said to have increased by 10 per cent to a total of 12,350 at the end of 1966. Although this implies a more rapid increase than that of the money being spent on research in physics, the Institute of Physics and the Physical Society is disappointed that its membership includes fewer than half of those eligible for membership.

The European venture is now apparently reaching a point at which decisions will be possible, and a steering committee under Professor G. Bernadini has been circulating the draft of a constitution for a federation of physical societies on a European basis. It is hoped that reactions to the proposals will be sufficiently well known by October or November for the steering committee to settle for a final version of the constitution. By all accounts, everything is going well, and the chances are high that by the end of the year or the beginning of 1968 a federal physical society will be in being.

Commercially, the Institute of Physics and the Physical Society continues to do well. In 1966 it was able to transfer £10,674 to the reserves on a turnover of £279,000. More than a third of its income comes from the sale of publications. This year, in contrast with 1965, profit on publications has been largely swallowed up by the cost of launching the new journal *Physics Education*—a venture which in commercial

terms cannot be expected to break even for some years after its foundation. In its report, the council has included graphs which show that the numbers of words of text printed in its journals are growing less rapidly than might have been expected. With the *Proceedings of the Physical Society*, for example, bulk has increased by only 50 per cent since 1961. The *British Journal of Applied Physics* has not grown in bulk since 1964.

At the meeting on July 4, Dr A. D. I. Nicol (Cambridge) was elected a vice-president of the Institute of Physics and the Physical Society, P. T. Menzies honorary treasurer, Dr R. Press honorary secretary, and Professors S. F. Edwards and C. A. Hogarth members of council.

## Hopeful Forecast

CONSIDERABLE improvements in weather forecasting were achieved during 1966, according to the report of the Meteorological Office for that year. Two reasons are given; first the acquisition of equipment for the automatic drawing of forecast charts for 48 hour forecasts (described in *Nature*, **214**, 230; 1967) and secondly an improved method for detecting the small scale changes which are one of the hardest problems of weather forecasting. This new approach uses a sophisticated model of the atmosphere, taking account of the water vapour in the air, and predicts pressure, temperature, wind and rainfall at hundreds of places 25 miles apart. To make the best use of the new method, though, the office will need a much faster computer; for a 24 hour forecast, the Atlas takes no less than eight hours to produce results.

The report preens itself a little about the report of the Estimates Committee of the House of Commons, which examined meteorological services during the year. Apart from congratulating the Meteorological Office on its efficiency, the committee seems to have agreed with the Office diagnosis of what needs to be done. A major expansion at Bracknell to overcome the shortage of space is one suggestion warmly welcomed by Dr B. J. Mason, Director of the Office. There also seem to be staff difficulties, principally in the scientific assistant grade where the recruitment rate cannot keep up with the resignations. There is also a shortage of experimental officers trained in experimental physics, electronics and computing, and these will have to be recruited on a much larger scale.

A new departure was the establishment of a Cloud Physics Branch at Bracknell. This includes a laboratory physics group transferred *en masse* with Dr Mason from Imperial College London, a cloud dynamics group, and a radar unit. To get the best from the branch, Dr Mason hints, new aircraft will be needed for the Research Flight. The Office has also flown experiments in rockets during the year, and one to study molecular oxygen in the British satellite UK 3. During the year regular direct reception of pictures began from the weather satellites launched by NASA; these have been very useful in weather analysis and forecasting. Difficulties of recruitment are aggravated by the lack of suitable university courses in Britain, and for some years the gap has been filled by the Meteorological Office Training School. Dr Mason reports that, at last, new accommodation has been found for the school, which will move from Stanmore to Shinfield Park in Reading at the end of 1968.

## Visitors to Britain

THE British Council seems to be pleased with the way its scheme for awarding scholarships for advanced study has been building up. In the present academic year, 126 scientists from various places are studying in Britain, most of them for periods of one academic year or more. Since 1963, the numbers of scholarships awarded to scientists have increased by roughly 50 per cent. At present, the pure sciences and technology account for 49 and 50 scholarship holders respectively. There is a steady trickle of half a dozen or so each year of people anxious to have first-hand experience of school science teaching in Britain. Most of the visitors to Britain under the scheme come from European countries—in the past four years there has been an especially rapid growth of business with Czechoslovakia, Hungary, Romania and Bulgaria, and 32 scientists from these countries are now in Britain under the scheme. 39 scientists have come from elsewhere in Europe and the scientists now account for more than a quarter—or, if awards to doctors are also included, more than 40 per cent—of the scholarships awarded by the British Council each year.

The ideal British Council scholar is a man or woman between 25 and 35. Although the awards cover cost of travel, tuition and maintenance, one snag may be that they are not always generous enough to keep all applicants in styles to which some of them may have become accustomed. Another difficulty, no doubt inescapable in arrangements of this kind, is that applications must be made roughly a year before the beginning of an academic year.

## New Chairman for CEI

MR LEONARD DUCQUER is the new Chairman of the Council of Engineering Institutions. He was elected on July 13 to the post left vacant by the death of Mr H. N. Pemberton on April 6, 1967. Mr Ducquer, 65, now takes office for a period of 18 months.

Mr Ducquer was educated at Haberdashers Aske's and the London Polytechnic Engineering College, and began his career with the British Thomson Houston Company in 1920. Until 1938 he worked in outside construction and contract engineering, and then moved to selling switchgear. BTH is one of the roots from which Associated Electrical Industries Ltd sprang, and from 1958 to 1965 Mr Ducquer was divisional director and general manager of the Heavy Plant Division of AEI. Since 1965, he has been a group consultant to AEI and a member of the board of AEI Automation. Mr Ducquer has been a member of the Council of Engineering Institutions for some years, and already has experience of its internal operations; he has been chairman of the overseas relations sub-committee and the finance sub-committee.

## Women Engineers

WOMEN feel that they are an underprivileged class, at least where engineering is concerned. This is what emerged from the last day of the Second International Conference of Women Scientists and Engineers, held last week in Cambridge. Delegates felt that the difficulty lay in attracting girls into engineering, as

there are always places for the determined few who wish to make it their career. The unfortunate view of engineering as a profession for those who like to get oil under their nails gives it a particularly unfeminine image, while very few schools are prepared to encourage their girls to do practical rather than academic science. Several speakers described how they met not only with discrimination in employment (a survey in Canada revealed that women engineers are better qualified than men in equivalent jobs) but also with some social hostility from their contemporaries, both male and female. Mrs Josephine Webb produced some interesting figures to show how strong these pressures are.

Table 1. ESTIMATED RATIO OF MEN TO WOMEN ENGINEERS IN VARIOUS COUNTRIES

	Ratio of men engineers to women engineers
USSR	3
Philippines	40
France	50
Sweden	60
USA	130
Britain	300
Japan	400
India	500
Canada	500
Republic of South Africa	4,000

There seems to be less prejudice against women as engineers in some developing countries than elsewhere. Delegates described how in India and the Philippines, women engineers can command well paid responsible jobs and become respected members of society. In Nigeria, however, the attitude of men towards women engineers is just as bad as in the West. One reason suggested for the "backward" attitude of the West was that the position of a woman as a mother is more highly regarded than her position as a technologist.

Most delegates agreed that the way to improve the situation is through education. Because most women who graduate in engineering go into industry, there is a shortage of teachers of technical subjects, and this does not encourage a more liberal attitude in the schools towards engineering as a career for girls. In future perhaps women engineers who cannot work full time because of their family commitments will be able to go into teaching part time, but this is by no means the whole solution to the problem. A delegate from Nigeria pointed out that one of the few positive things many women engineers can do is to have daughters, and bring them up with a different attitude to technology.

## End of an Era?

THE UK Atomic Energy Authority has been saying goodbye to Sir John Cockcroft, the first director of the Atomic Energy Research Establishment at Harwell and a member of the UK Atomic Energy Authority since its formation out of the atomic energy research group at the Ministry of Supply in August 1954. Sir John has been Master of Churchill College, Cambridge, since 1959, and a part-time member of the board of the AEA since that time. Although Sir John does not retire officially until the end of this month, his colleagues on the AEA found his last appearance at a board meeting on July 6 something of a wrench.

Within the AEA, Sir John is most affectionately regarded for the intellectual stature which he gave to the Harwell establishment from its beginning

more than twenty years ago. For several years, the laboratory was an exceedingly unusual compromise between a university and a successful industrial laboratory. Harwell also managed under his guidance to avoid the worst excesses of too much security. To have demonstrated the artificial disintegration is obviously as much a help when dealing with policemen as with other physicists.

As is the modern custom, there seems to be no prospect that retirement will allow Sir John to do less work. For one thing, of course, being the head of a Cambridge College is enough to keep many other people fully occupied. Among the extra-mural activities on which he is engaged, however, becoming President of the Liberal Party next year will be particularly interesting, if only because it will provide an opportunity for a distinguished but never compliant public servant to say many things which have not been possible while on the government payroll. The first benefits—which will not everywhere be acclaimed as such—could come quite soon.

## More Uranium in South Africa

THE most interesting feature of the report of the Atomic Energy Board of the Republic of South Africa is that the search for uranium and thorium reserves has been renewed. The board feels that in the foreseeable future the demand for uranium will exceed the supply, and hopes to find new reserves in South Africa. Whatever the reserves of uranium, there seems to be plenty of thorium, although the report admits that as yet there is no market for it. Apparently reserves of monazite in the Karroo system exceed 200,000 tons, and contain over 7 per cent of thorium dioxide, while there are 163,000 tons of slightly poorer ore, containing between 5.5 and 7.0 per cent of thorium dioxide. The board believes that once large scale converter and breeder reactors come into use, there will be an assured market for thorium. In addition to exploration, work has been continued on the solvent extraction of uranium directly from leach liquors, cutting out the ion-exchange absorption step.

The report also conveys some idea of the reactor types which the board is studying. The main effort is being devoted to a reactor called Pelindaba, a name incorporating both the name of the laboratory—Pelindaba—and the chemical symbols for deuterium, uranium, and sodium. This reactor, as its name indicates, is fuelled with slightly enriched uranium (2 per cent), moderated with heavy water, and cooled by sodium. The lay-out of a 30 MW prototype is now in an advanced stage and is intended as a first step towards a 300 MW electrical station. The fuel will be in the form of spheres of either metallic uranium or uranium monocarbide, and sphere sizes in the range 2 to 4 mm are being contemplated. So far 1 cm spheres have been produced, but smaller ones are being produced by the lead shot technique in which molten droplets of uranium solidify as they pass through a column of fused salt. The monocarbide pellets, on the other hand, will be produced by die-pressing, arc-melting, or possibly a sol-gel process.

The third major aspect of the board's work is concerned with applications of radio-isotopes and radiation. This includes radio-isotope production, environmental radioactivity, and some fundamental

studies in nuclear physics. Biological, chemical, and waste problems have also been considered. The cost of the board's activities is divided into two accounts; one, covering salaries, clerical costs, equipment, conferences and subscriptions to international organizations, amounts to R4.46 million (£2.23 million). The other account is called the research fund, covers capital and running costs and amounts to R4.44 million (£2.22 million).

## New Look for Birmingham

THE new technical University of Aston in Birmingham will be "an urban residential university, intimately linked to the life and needs of Birmingham and the Midland region" according to the development plan now published.

The university, formerly the Birmingham College of Advanced Technology, will be expanded on a thirty acre site next to the existing four acres at Gosta Green in the centre of Birmingham. Because of the limitation in space, the university will presumably be built rather more up than out, with five new teaching blocks of seven or eight storeys dwarfing the single and double storey heavy engineering and research laboratories. These blocks will eventually house the whole of the engineering and social science faculties. The existing building will be extensively renovated for continued use, primarily by the science departments.

The university hopes to expand its student population from the present total of 2,300, with 10 per cent postgraduates, to a total of 5,500 with 27 per cent postgraduates in the late seventies. There is an intermediate target figure of about 3,300 students in 1971–72. The largest increase will be in the social sciences, from about 140 students, 6 per cent, to about 1,200, 22 per cent. The number of students in science will increase from about 760, 33 per cent, to about 1,650, 30 per cent; engineering will expand from about 1,400 students, 61 per cent, to about 2,650, 48 per cent. It is hoped that the expansion of the social science faculty will reflect the increasing need for scientists and technologists to be aware of the demands and techniques of management. Introductory management studies at undergraduate level should give an appreciation of the organization, control and economic background of modern industry.

Advisory services to industry are mentioned in the university's charter, and it is to this end that the Department of Economic Affairs has given a grant of £51,650 per annum for five years to set up a centre for the study of small businesses.

## Intricacies of Bacterial Cell Walls

from our Correspondent in Microbiology

THE cell walls of bacteria differ from those of other organisms in several remarkable ways. Subject to considerable mechanical stresses, they are, nevertheless, highly dynamic structures and their chemistry and structure are of a complexity not usual in other cells. It is in the Gram negative bacteria that the nature of the cell wall appears at its most intricate. Several chemical analyses have been made of these bacteria, but only within very recent years have useful correlations been offered between these and fine structure

data. The work of Weidel and his colleagues has been paramount in establishing the basic chemistry of the *Escherichia coli* wall, while de Petris has attempted to identify various layers seen in electron micrographs with these chemical components. Unfortunately, correlations of this kind are founded on indirect evidence alone, and various interpretations have been made.

De Petris has sought to substantiate his own views by subjecting *E. coli* cells to a variety of chemical, physical and enzyme treatments and has checked any changes which were produced by electron microscopy (*J. Ultrastruct. Res.*, **19**, 45; 1967). There is general agreement that the cell wall of this bacterium has an asymmetric, multilayered construction comprising an outer triple layered zone (the *L* membrane), an intermediate zone (the *G* layer) and a less well defined, electron transparent *M* layer. By heat treating cells and thereby denaturing autolytic enzymes, de Petris found the *G* layer could be further resolved into  $g_1$  and  $g_2$  substructures. When the cells were incubated with proteolytic enzymes such as papain or pepsin, the  $g_2$  layer separated from the external *L* membrane appeared free of other material and, significantly, maintained the original cell morphology. Subsequent digestion with lysozyme removed the  $g_2$  layer. Similarly the combined action of lysozyme and EDTA was effective in eliminating this structural entity. The obvious interpretation is that  $g_2$  is wholly or in part composed of mucopeptide (murein). Isolation of the "murein sacculus" (*sensu* Weidel and Pelzer) by successive enzyme and detergent treatments and demonstrating it to have an identical appearance to that of the  $g_2$  component is compelling confirmation of this suggestion.

Subjecting the lipid-containing *L* membrane to phenol attack reduced the total wall structure to a single electron opaque zone, possibly the equivalent of  $g_2$ ; milder detergent treatments produced a similar result, but one less frequently obtained. Lipopolysaccharides which are extractable in phenol-water mixtures had a triple layered organization but are more likely to be preparative artefacts rather than *L* membrane fragments *per se*. The nature of the *M* layer remains an enigma and it is by no means certain whether it represents free space or a solid matrix. An interesting suggestion of de Petris is that it could be a site—together with the  $g_1$  layer—of surface bound enzymes.

The model of *E. coli* walls erected by de Petris is in accord with that proposed by the Munich group (see Martin: *J. Theoret. Biol.*, **5**, 1; 1963) and is a significant refinement of it. Differences in detail are obvious, particularly in the interpretation of the lipid and protein constituents. But obvious also are the unanswered questions about the character of the *M* layer and the structural protein, the role of the latter and other materials in imparting rigidity to the murein sacculus and the dearth of really comparable data on other Gram negative species. Finally, the walls of Gram positive bacteria, generally regarded as being homogeneous in construction, are also being resolved into a complex with several layers. The elegant analysis of *Bacillus polymyxa* walls by Nermut and Murray (*J. Bact.*, **93**, 1949; 1967) demonstrates forcibly the chemical heterogeneity and structural differentiation which can occur in Gram positive cells.

## Parliament in Britain

### Sonic Booms

IN reply to a written question in the House of Commons on July 4, the Minister of State, Ministry of Technology, Mr J. Stonehouse, announced that it had been decided that during the month of July Lightning aircraft from the Ministry's Aeroplane and Armament Establishment at Boscombe Down should be permitted to fly supersonically over various parts of Southern England in such a way as to create sonic bangs. The intensities, he said, would be well below those likely to cause damage. The flights will be confined to the hours of daytime, and will be monitored by technicians from the Royal Aircraft Establishment, Farnborough.

### Costs of Technology

MR A. WEDGWOOD BENN, Minister of Technology, stated that over the last 10 years £151 million has been spent on the Atomic Energy Research Establishment, Harwell, £73 million (including £10 million contributed to the international Dragon project) on the Atomic Energy Establishment, Winfrith, £15.5 million on the National Engineering Laboratory and £36.3 million on the National Physical Laboratory (including since April 1, 1965, expenditure on the National Chemical Laboratory). (Written answer, July 4.)

### Teacher Training

MR G. ROBERTS, Minister of State at the Department of Education and Science, gave figures for students successfully completing courses of initial training in colleges of education 1953–63 as follows: 1952–53, 2,290 men and 8,165 women. For 1953–54, the corresponding figures are 2,331 and 8,119; for 1954–55, 2,361 and 8,403; 1955–56, 2,513 and 8,609; 1956–57, 2,537 and 8,891; 1957–58, 2,709 and 9,248; 1958–59, 2,991 and 9,559; 1959–60, 3,588 and 10,092; 1960–61, 4,160 and 10,360; 1962–63, 4,254 and 9,591. (Written answer, June 30.)

### Traffic Control

LORD SHEPHERD, for the Ministry of Transport, gave news of developments in the control of traffic in London by computer. He said that the ministry intended to introduce computer controlled traffic lights to phase traffic flows, and experiments would soon be beginning in West London. The Greater London Council were involved in the West London experiment, and were already considering extensions of traffic control by computer in London. He admitted that the scheme had been held up since 1963, and explained that the delay had been caused by the time taken to design and build the computer. (Answer, House of Lords, July 6.)

### Sea Bed

MR ANTHONY CROSLAND, Minister of Education and Science, in reply to a question by Mr T. Dwyer on what studies were being made of the possibility of greater exploration of the resources of the sea and sea bed by the UK, said that two initiatives had recently been taken. The Government had initiated a review which would examine what additional work would be profitable and how such work could be put into effect and co-ordinated with existing activities. Also the NERC was examining the extent to which it would be justifiable and practicable to expand its exploration of the Continental Shelf, with particular reference to economic returns and the needs of the extractive industries. (Written answer, July 3.)

# Planning for Food

by our Special Correspondent

What can science and technology contribute to what is called the world food problem? President Johnson's Science Advisory Committee has been studying this question. It has nothing new to suggest, but it does consider that if the next twenty years can be endured, the more distant future should be supportable.

SOLVING the food problems of the world is a massive problem, as President Johnson recognized when he asked his Science Advisory Committee to investigate it. The committee has now come up with a massive response, in size at least, in the shape of a report of three volumes and more than 1,000 pages. Fortunately, the bulk of the report is summarized in volume 1, *Report of the Panel on the World Food Supply* (US Government Printing Office, Washington, D.C. 60 cents).

The report is subdued, almost detached. The facts it records are not new: "We have been unable to devise any new or original statement of the world food problem". So often and so thoroughly has the problem been described that the panel feared it was becoming obscured by "rhetorical overkill". Clearly it set out with the intention of avoiding this trap, at least, and it is successful. The facts alone are alarming enough, without the need for oratorical excess.

The report first deals with common delusions about the food problem, before it gets down to discussing it in detail. Overpopulation and the shortage of food are separate but interrelated problems: "the choice is not to solve one, or the other; to solve both is an absolute necessity. The tendency to think of food production and fertility control as alternative solutions to a common problem is dangerously misleading". The panel also admits that solving the food problem can never be as exciting as other, more dramatic projects: "It is dependent on far-reaching social reforms and long range programmes of hard work which offer no promises of quick and dramatic results so helpful in maintaining enthusiasm for a concerted, difficult undertaking". There are, it says, no buildings to dedicate, no vehicles to launch into space, just toil, year in and year out. Equally, the panel has no new solutions to offer; indeed, it seems to distrust solutions because they tend to distract attention from the fundamental problem, which is that the shortage of food is only one part of the enormous problem of economic development in the poor nations.

The main panel was chaired by Ivan L. Bennett, jun., who is deputy director of the Office of Science and Technology, and thirteen sub-panels were set up to tackle all aspects of the problem. The broad philosophy of the panel was to study food production in the context of the more general questions of economic development and foreign aid. First, the report defines the scale of the problem: by 1985, the world will need 52 per cent more calories; even if the most optimistic view of birth control programmes is taken, the need will still be for 43 per cent more than today. These figures are presented in the context of a world situation in which the total amount of food in the world, both in quality (protein) and quantity (calories), is adequate. Only the uneven distribution of food between countries, within countries, and among families with different incomes has caused the problem, the report states. The panel was confident that the next twenty years would be the critical period, since after 1985 family planning programmes will ease the pressure. If the problem is solved within the next two decades, the report concludes, "it will be manageable thereafter".

Fig. 1. Projection of calorie requirements for the world, India, Pakistan and Brazil.

The falling mortality rate among children is often quoted as a cause of the population explosion, as indeed it is, but paradoxically the panel believes that it can also reduce rather than increase the rate of population growth. This will happen when families are finally freed from the tyranny of having to have at least four children in order to ensure that one son will survive. In this view, lowering mortality rates is an essential pre-condition for the acceptance of birth-control methods, which are an irrelevance until couples have secured the desired number of living children.

Ideas about agriculture itself must also be changed, the report suggests. For centuries, farming in underdeveloped countries has been carried out at subsistence level, producing only enough food for family or local needs. Farmers in these countries must be converted to a commercial system in which production is for markets at a distance from the farming area; "fundamentally, it appears that many nations are under-utilizing the power of the market economy". Mexico, apparently, is an exception, and the panel gives it a pat on the back. Not only must farmers be expected to change, but the situation must be rigged so that the pay-off for change is enormous — "not 5 to 10 per cent, but 50 to 100 per

cent". This needs a system of farm credit enabling farmers to buy essential "inputs"—seeds, fertilizers, and pesticides—without financial risk, at least at first.

The panel is pessimistic about unconventional sources of protein, or about food which requires people to change their traditional eating habits. Habits certainly cannot be changed in the short run, and even in the long run changes must be carefully planned. As for unconventional approaches, the report declares that there are no panaceas. Single cell protein, derived from fermentation by yeasts or bacteria of carbohydrates, hydrocarbons or cellulose, seems the most promising, but there are unsolved problems of production, processing quality, consumer acceptance, and cost which remain to be worked out. Methods of extraction of protein from green leaves exist, but again there are problems, and the use of algae has so far been unrewarding because of the excessive cost of producing a product fit for human consumption. The conclusion is that the vast majority of increased food production must come from the developing countries themselves. Animal sources, including fish farming (which the panel calls aquiculture) and developments such as fish protein concentrate, can help, but most of the increase must come from agriculture.

Having worked out what will be needed, the panel goes on to estimate what it will cost. The conclusion is that to pay for an increase of food production at the compound annual growth rate of 4.0 per cent per year, gross national income in the developing countries will have to grow at 5.5 per cent per year. Laconically the report says, "The achievement of such growth rates will require massive efforts which must be more successful than history has recorded in any previous 20 year period". Current growth rates are of the order of 4.5 per cent per year, and only Mexico and Taiwan are achieving growth rates of the order necessary. The additional capital requirement if food production is to rise at the rate required will be \$300 million annually in the early years, rising to almost \$4 billion by 1985. To do this, the United States will be powerless alone, and should instead take the lead in mounting a global effort.

How will agricultural production be able to increase at this rate? First, the panel believes that an inadequate proportion of the world's surface is at present under cultivation. The amount of potentially arable land is 24 per cent of the Earth's surface, but less than half of this has ever been cultivated in the past twenty years.

In any given year, only a third of this area is harvested. In Asia, unfortunately, rain is so rare over some of the potentially arable land that even one four-month growing season is impossible, and there is no hope of increasing the area harvested. Production must be pushed up by increasing yields per unit area, or by double or triple cropping based on irrigation development. The situation in Africa and Latin America is different; here the limitations are not of potentially arable land, but are economic, institutional and social problems. Secondly, the panel favours the adoption of improved crop varieties. Some of these are mentioned: rice varieties which originated in Taiwan, and were developed at the International Rice Research Institute; dwarf wheat varieties developed in Mexico; maize varieties developed in Tropical America; and sorghum genotypes which possess wide ranges of geographic adaptation.

Although brief mention is made of the contribution which new technologies can make in food production—weather and climate modification, and weather studies by satellite—the conclusion is that the technology needed is at hand, if only it can be applied. In this connexion, AID, created in 1961 as the US umbrella organization for aid, comes in for some criticism. Since AID took over the technical assistance programme, the reports says, weaknesses and lack of quality have clearly grown worse. AID finds it hard to recruit high-quality personnel, a difficulty not shared by the Department of Agriculture, or the Department of Health, Education and Welfare. Both departments have found it harder to provide assistance overseas since AID came on to the scene. Both the short term contracts from AID and the fact that the departments are not involved in the planning stage of projects hold back effective development. "Consequently, through a combination of factors, these agencies, which . . . are best able to conduct programmes of technical assistance overseas, are largely excluded from programme planning and limited to short term activities". Another organization should be sought which could involve the Federal agencies more effectively, and, although the change would be difficult, the panel recommends a new co-ordinating and funding agency to oversee the foreign aid programme. The distinction within the Federal establishment between domestic and foreign aid should be abolished, so that the entire manpower and expertise of the agencies can be made available for foreign aid, without subterfuge or indirection.

## Parliament and Nuclear Power

by  
NIGEL HAWKES

In December 1966 the House of Commons established the Select Committee on Science and Technology. The committee, thirteen strong, began with an examination of the nuclear power programme in Britain. It has finished taking evidence, so that it is possible to guess what the committee may recommend—and whether the experiment has been a useful one.

THE Select Committee on Science and Technology has finished taking evidence on the British nuclear reactor programmes. Before the members can write their report, they must sift through a pile of detailed written memoranda and more than thirty hours of oral evidence. Is it all waste paper? Did the committee ask the right questions, or understand the answers? Is there any real hope that non-specialist committees of this sort can provide worthwhile advice?

The committee set out with a fund of goodwill, announc-

ing that it would operate in public, and would not hesitate to call ministers to give evidence, if necessary. Its first mistake was to call Sir William Penney, Chairman of the UK Atomic Energy Authority, to open the oral evidence. The position of the AEA is fundamental to the entire issue. Chronologically, it may have seemed tempting to begin with it, but it was a temptation that should have been resisted. At least one of the interviews with Sir William, who saw the committee twice, should have been held at the end of the session, when the committee was

better acquainted with the issues. In the event, Sir William was charming, lucid—and essentially uninformative.

Perhaps Mr Stanley Brown of the CEGB should have performed first. It was not, of course, that Mr Brown had anything rude to say about the AEA, or about anyone else; one of the committee's problems has been that most of the witnesses have been so appallingly good mannered that interpreting their evidence became a question of reading minutely between the lines. Only rarely did witnesses say precisely what they meant; Lord Robens, and Colonel Raby of the Associated Power Company, were the most refreshing in this respect. This makes it vital to ask the right questions, and it certainly became clear that the committee was getting better at this as time progressed.

Several red herrings were chased in connexion with technical problems. Had the change of channel diameters which the Central Electricity Generating Board had sanctioned for the Hinkley *B* contract really cost more than £10 million? And then there was doubt about whether it would be better to standardize designs for the Advanced Gas-cooled Reactor or to allow technical development free reign. On the argument between the AGR and the Boiling Water Reactor, there was doubt whether the Dungeness *B* appraisal of the CEGB truly represented the costs of the designs. The committee really made no headway with these problems.

Too often, it found, the answers rely on technical value judgments—how much more development is to be had from the AGR, or what importance is to be put on outage (the time power stations are out of action through shut-downs). On questions like these, the committee could not compete with the accountants of the CEGB or the scientists of the AEA—and nobody seriously expected anything else. In Britain, there is no organization which can argue successfully with the AEA, a situation highlighted by the frank admission to the committee by the Minister of Technology that there is nobody in his ministry who is capable of checking the figures sent to him by the AEA.

When the problems of the structure of the industry or its export possibilities were discussed, the committee was much happier, even though the political inclinations and disagreements of committee members could not be concealed. Mr Tam Dalyell, for instance, seemed at times to be suggesting that there is no need for internal competition supplied by three consortia, since General Electric and Westinghouse supplied all the competition anybody could ask for. Other members were better disposed towards the consortia, but the probable outcome will be a recommendation that there should be only two consortia, formed by mergers across the board between the existing consortia, or by breaking up one consortium completely.

As for the AEA, the committee can hardly do anything but endorse and encourage the rundown of effort which is already under way. It would, for example, be surprising if the AEA were told to become a consortium in its own right, tendering for stations and looking for overseas business. Equally, it is unlikely that the committee will have anything kind to say about the diversification upon which the AEA is somewhat breathlessly engaged. The Ceramics Centre and Non-Destructive Testing Centre recently set up at Harwell will probably be criticized. While the committee recognizes what a splendid organization the AEA has been, it is likely to take the view that for too long the AEA has been sucking in talented people who might otherwise have improved the technical quality of the consortia. The CEGB may perhaps come off best of all, although it will certainly be criticized for its handling of the Hinkley Point *B* contract. Apart from matters such as the research programme of the CEGB, it is difficult to see what the committee can recommend—Mr Duncan Burn's suggestion that the CEGB should be divided into three competing groups will probably get short shrift.

One thing is clear. The committee was thoroughly dissatisfied with the export performance of the British consortia, and is certain to suggest ways in which it could be improved. The British Nuclear Export Executive, it is likely to feel, is too small and unambitious to be effective. Either it will be told to expand, or to make way for another organization with a sales force abroad. One possibility here is that the committee will try to find a way of using the prestige of the AEA abroad as an element in the export organization.

The value of the committee's work will clearly depend on its collective judgment, which is still uncertain, but the balance of forces on the committee indicates a conservative report along the lines suggested. The chairman, Mr Arthur Palmer, is a middle of the road Labour back-bencher, who has controlled the committee without apparently antagonizing it, but without firing it with any great enthusiasm either. The most effective member has been the only Liberal, Mr Eric Lubbock, who has been particularly good on technical subjects. He has also been persistent, and emerged from a memorable clash with Lord Robens as a winner on points. Of the rest, Mr Ernest Davies and Mr Tam Dalyell have both been effective in their different ways—Mr Davies patient and eminently reasonable, Mr Dalyell abrupt. There has been little direct axe-grinding, either on constituency or party issues, although Mr David Ginsburg has taken the opportunity of digging for information about the coal-fired power station, Drax, which is being built in his constituency. Defence issues have been studiously avoided except by the indefatigable Mr Norman Atkinson, who announced at an early session that he was a member of the Campaign for Nuclear Disarmament, but later remembered that he was merely a supporter, without actually belonging. At times he has been frustrated by the good manners of the committee, which have sometimes prevented it from pinning down evasive witnesses. There have been no such inhibitions for Mr Atkinson.

The Conservative members, to be honest, have been less effective. Sir Harry Legge-Bourke, prefacing each question with detailed references to memoranda and transcripts of previous meetings, has sometimes seemed as likely to confuse the committee as the witnesses. Mr David Price, the Conservative Front Bench spokesman on science, has been lucid. In general, though, the most effective members of the committee have been those who attended most often, and in this respect the Conservatives—with the exception of Sir Harry—have a poorer record. The general attendance has been remarkably good; although the quorum for the committee is only four, there has never been an occasion when the numbers have fallen below eight or nine.

Although the committee has so far done fairly well, there are no grounds for unbounded optimism. In considering reactors and nuclear power, the committee at least had an industry into which it could get its teeth. The problems, in fact, were as much economic as they were scientific. Other issues will not be as kind to the committee as this; it is alarming to think, for instance, what would happen if the committee were to discuss highly technical subjects, such as the justification for a British investment in the CERN big machine, or the grant giving policy of the Science Research Council. These are problems in which finance and high level scientific judgments are closely interwoven. What the committee needs is much larger staff of its own, working full time on the technical problems, but unfortunately this idea is a pipe-dream. With recruitment to the House of Commons staff at present levels, it is lucky even to have a clerk to look after its business. These criticisms may seem unduly harsh, and perhaps they are; there are certainly advisory committees a good deal less competent than the Select Committee, even on technical issues. The only difference is that the Select Committee has had the courage to do its agonizing in public. It should be encouraged to continue.

# The Student's Microscope

by

JOHN R. BAKER

Department of Zoology,  
University of Oxford

How suitable are modern students' microscopes for teaching undergraduates? Dr Baker has been investigating the ergonomics of microscope construction for several years.

THIS article is based on the opinion that the microscope provided for use by undergraduates should include all the really fundamental constituent parts of the more elaborate instruments intended for research, and should be convenient for use not only by the student but also by the demonstrator.

To find out whether the modern student's microscope fulfils these conditions, visits were paid to nine of the principal manufacturers of the world (three British, two West German, one East German, and one each from Austria, the Soviet Union and the USA). Attention was concentrated in each case on the instruments recommended by the manufacturers for use by undergraduates in the biological departments of universities. Each instrument was examined in detail in the presence of an expert representative of the firm.

It was found that with certain exceptions the instruments tended to conform rather closely to a single type. The lenses were generally of high quality, and the mechanical parts, particularly the fine adjustments, were in most cases of good design and well made. Nevertheless, the instruments did not fulfil the requirements set out in the first paragraph of this article.

In what follows, the requirements that concern the student directly will be considered first, and attention will then be directed to the needs of the demonstrator.

In the typical modern student's microscope, the illuminating apparatus is an integral part of the instrument. It usually consists of an electric bulb placed in the optical axis, with a plano-convex lens above it. The plane surface of the lens, slightly roughened, faces downwards. The distance between the convex upper surface of the lens and the lower focal plane of the substage condenser is so short that it is impossible to provide a field stop, for this would inevitably act as an aperture stop. Accurate focusing of the condenser is impossible. It is commonly recommended that this lens should simply be raised as high (or nearly as high) as possible<sup>1</sup>, or put in such a position that the roughened surface of the lamp lens does not obtrude on the field of view<sup>2</sup>. Centring screws for the condenser are not usually provided.

This method of illumination does not lead to the best possible image, partly because the absence of a field stop may result, with certain objects, in the defect technically termed 'glare', partly because an unfocused substage condenser may give too small an aperture for the effective use of an oil immersion objective, and partly because the condenser is often slightly or even markedly eccentric, so that the illumination is somewhat oblique. An even more serious objection to the method of illumination

employed in the modern student's microscope is that the student graduates without ever having learnt the basic principles that should guide him in the subsequent use of a first-rate instrument. He does not know how to focus the condenser accurately, how to centre it, or how to use a field stop to control glare. This lack of elementary knowledge, combined with an ingrained insensitivity to defects in the image, is an obstacle to progress if the student subsequently undertakes research. If he becomes a teacher, he will not encourage high standards in microscopy.

It would not be difficult to provide the student with a more satisfactory method of illumination. There is no reason why the lamp should not be an integral part of the microscope: the objection is only to its situation so close to the lower focal plane of the substage condenser that a field stop cannot be provided. The need for compactness has been greatly exaggerated, at the expense of the optical performance of the instrument and of its suitability for instruction in the basic principles of microscopy.

Köhler illumination in its usual form would be too expensive for incorporation in the student's microscope, because of the necessity to provide a transformer and resistor; but a convenient and inexpensive substitute, giving ample illumination for low-power dark ground work and for phase contrast with the 4-mm objective, is 'large-source Köhler illumination'<sup>3</sup>. In this method light is provided by an ordinary domestic electric bulb of about 100 W. The 'pearl' surface of the glass is focused by a simple plano-convex lens on the lower focal plane of the substage condenser. The field stop (an iris diaphragm or set of interchangeable stops) is placed sufficiently far from the mirror to allow its effective use. The lamp is an integral part of the microscope. It may be placed in front of or to one side of the instrument. The intensity and colour of the light are controlled by a few filters, fitting into sockets in the substage.

The substage condenser should be provided with centring screws. In microscopes that lack these screws, this lens is often markedly eccentric, as has already been mentioned; and in any case it is desirable that the student should be familiar with the process of centring the condenser, so that he may be capable of using more elaborate instruments.

Every student of biology at a university should be familiar with phase contrast. The method is invaluable in class work with living cells of all kinds. The expense can be kept quite low. There is no need to provide students with complete sets of phase contrast objectives. The phase contrast effect is more striking with objectives

of focal length about 4 mm than with those of lower or higher power. The presence of the phase annulus in the 4-mm objective need not cause any serious deterioration in the image when it is used for direct ('ordinary') microscopy, provided that the amplitude reduction in the annulus is rather high. A single objective would suffice for both purposes if enough money were not available for the purchase of two. The illuminating annulus can be held in a mount arranged to be pushed into the substage from below. It is necessary to provide centring screws for this mount (separate from those for the condenser). It is unnecessary for each student to have a telescope for centring the illuminating annulus: one can be shared among twenty or more students, as the centration will not be readily undone by slipping the mount in and out.

Every biological student should use polarized light, where appropriate, as a matter of course. Much useful work can be done with a polarizing film in the substage filter tray and another in a mount to slip over the eyepiece. With a little ingenuity it is not difficult to provide a couple of compensators (red of the first order and a quarter wave plate) and to ensure that these are correctly orientated in relation to the plane of vibration of the polarizer. With this simple equipment the student can instantly distinguish positively from negatively birefringent objects.

The angle of the microscope tube is a matter of special importance in the teaching laboratory. The stools provided in classrooms are usually of the same fixed height. In these circumstances the vertical tube is convenient for both student and demonstrator. The sitting heights of students vary greatly, and it is easier for persons of different heights to adapt themselves to vertical tubes than to sloping ones, provided that the eyepiece is not too high. A tall student has only to let the head fall slightly forwards, into what is in fact a position of rest. If a sloping tube is of the correct height for a short student, a tall one can only use the microscope by pushing his seat back, leaning far forwards, and then throwing his head backwards into a position that involves considerable strain.

It is for the demonstrator, however, that the sloping tube is particularly inconvenient. As a general rule students are unwilling to vacate their seats when the demonstrator approaches, unless for some reason it will obviously be necessary for him to sit down. The result is illustrated in Fig. 1. The student leans back in her seat; the demonstrator, standing, has to put his head where hers was. To do this necessitates the assumption of a very inconvenient attitude. He must bend low: indeed, if he is tall his back will be almost horizontal. He must turn his head to left or right (according to the side on which he is standing), and at the same time bend it strongly backwards. To do this repeatedly over a period of two or three hours is extremely irksome and tiring. With a vertical tube the demonstrator has only to lean forward. He need not turn his head to right or left, and there is no question of bending it backwards. His position involves no strain or discomfort.

If asked, many microscope manufacturers will provide a vertical tube intended for use in photomicrography, to replace the sloping one of the modern student's microscope. It cannot be too strongly emphasized that this simple change does not solve the problem. The sloping tube of the modern student's microscope is so placed that it is convenient for students of average sitting height when there is the usual difference in height between seat and bench. If the sloping tube is replaced by a vertical one, but the microscope remains in other respects unchanged, the eyepiece is far too high for comfortable vision by most students, and the instrument is actually unusable by those whose sitting height is low. The presence of the whole illuminating system below the stage makes it necessary that the latter shall be high, and this means that the eyepiece is too high if a vertical

Fig. 1.

tube replaces the sloping one. A fundamental change of design is necessary if this replacement is to be made. With the system of illumination suggested in the present article there is no reason why the eyepiece should be at an inconvenient height even for short students.

If students were given adjustable seats, they could all use the sloping tube conveniently, but it would be necessary to provide their microscopes with vertical tubes in addition, for the convenience of the demonstrator. This could be achieved by the use of a beam splitter or a tilting mirror. The problem would now be to make it possible for both demonstrator and student to see the former's pointer, which is one of the most essential pieces of equipment in the teaching laboratory. The familiar pointing eyepiece could obviously not be used, unless the student were to use the vertical tube when looking for the object indicated by the pointer. The best plan would probably be to place a movable pointer in the plane of the field stop, as this plane is conjugate with the field of view when the substage condenser is accurately focused. The same part of the object would necessarily be indicated in both eyepieces. Even an ordinary Abbe condenser gives a sufficiently clear image of such a pointer when a 4-mm objective (or any lower power) is used.

It is unnecessary for the demonstrator and student to see the object at the same time, and indeed this would be rather embarrassing, from the proximity of the two heads. The only requirement is that, when the demonstrator has set the pointer by use of the vertical tube, exactly the same point will be indicated to the student when he looks through the sloping tube.

It is sometimes suggested that the demonstrator need not look through the student's microscope, because he can teach by using the projection microscope. I have already, however, listed seven reasons why this is not so<sup>4</sup>. Here it must suffice to say that the projection microscope is a useful adjunct to the lecture room, but looking at projected images is not practical work and teaches nothing about microscopy.

# Point Holograms as Optical Elements

by

A point hologram is formed on a photographic plate when a spherical wavefront interferes with a plane or another spherical wavefront. Such holograms behave like lenses or mirrors, but are easier and cheaper to produce and may replace them for certain applications involving coherent light. It seems to be feasible to make them very much larger than conventional optical elements.

THE principle of reconstructing wavefronts by means of holograms<sup>1</sup>, which is now practicable using laser light sources<sup>2</sup>, has usually been applied to reconstituting the wavefronts beyond finite objects, in order to reconstruct images of such objects. It should also be possible, however, to reconstitute holographically the wavefronts emerging from good quality lenses or mirrors and thus to use such holograms as optical elements, replacing some of or all the lenses in an optical system. This has been our aim, and the principle is quite independent of the object or test region to be imaged. Because the essential property of the optical elements is that they have a focus—that is, that they will transform an incident plane wavefront into one diverging spherically from a fixed centre, such replicas of optical elements would be essentially holograms of wavefronts emerging from a point; they are therefore referred to as point holograms.

A point hologram is the fringe pattern produced by the interference of the spherical wavefront to be reconstructed with a plane wavefront (see Fig. 1) or with a wavefront of different curvature (see Fig. 2). The point hologram has a focal length and behaves like any other imaging device, except that it brings about a change in the curvature of the wavefront by diffraction rather than refraction or reflexion. If its focal length is  $\pm f$ , the position of the point image, at a distance  $b$ , when the hologram is illuminated with a wavefront of radius of curvature  $a$ , is given<sup>3</sup> by

$$\pm \frac{1}{f} = \frac{1}{b} - \frac{1}{a} \quad (1)$$

Our particular field of interest is the study of such phase objects as occur in the investigation of flames or events in wind tunnels, by methods including schlieren, shadowgraphy, deflection mapping and interferometry<sup>4</sup>, and the application of laser light sources to such optical systems<sup>5,6</sup> has already proved most promising for studying phase objects at very high time resolution<sup>7</sup>. Because the cost of a schlieren mirror of the dimensions calculated later as feasible would lie in the range of several hundred to several thousand pounds and that of an equivalent lens would be quite prohibitive, there is some practical point to this study, in addition to its intrinsic academic interest.

**Making point holograms.** Point holograms of various focal lengths were made using a Mach-Zehnder interferometer by interfering a spherical wavefront emerging from a telescope objective with a planar reference wave. The essential part of the apparatus is shown in Fig. 1. The holograms were recorded on 'Ilford R52' plates, using as a light source a 1 mW helium-neon gas laser operating under single mode conditions. The intensity of the two interfering beams should be arranged so that the information is recorded on the linear portion of the photographic emulsion's amplitude transmission against exposure characteristic<sup>8</sup>. This is achieved by adjusting the intensity of one of the beams so that the transmission of the plate corresponds to the centre of the linear portion of the

characteristic: the addition of the second beam, if of sufficiently small intensity, will modulate the background by forming interference fringes the transmission of which still falls on the linear portion of the characteristic. Although it would be more economical of light to develop the hologram to a lower density, it will be shown that the intensity of solid state lasers makes a loss in the quality of reconstruction unnecessary.

It will be noted that the reconstruction process gives rise to two spherical wavefronts; one originating from a virtual point behind and the other from a real point at the same distance beyond the hologram. The distance between these points and the hologram corresponds to the focal length. The reconstructed spherical wavefront can, however, be separated from the planar wavefront illuminating the hologram only if the scene beam and reference beam are inclined to one another during the

Fig. 1. R, Reference beam; P, photographic plates; S, scene beam; H, point hologram; M, semi-silvered mirror. For explanation see text.

Fig. 3. Concentric circular fringe pattern.

recording process (Fig. 1b). If the emergent wavefronts are not separated they interfere with each other, forming a series of concentric circular fringes as shown in Fig. 3. Separation is essential if the hologram is to be used as an imaging device, for the image plane will otherwise be smothered by the circular fringe pattern.

In practice it is not necessary to use any device such as a Mach-Zehnder interferometer for making point holograms. This is fortunate because in order to make the large aperture point holograms mentioned later, correspondingly large planar optical elements would be needed as beam splitters and mirrors. Point holograms of any desired focal length can be made by interfering two wavefronts of different curvature. The resulting focal length is given by equation (1), where  $a$  and  $b$  now refer to the respective distances from the two centres of curvature of the wavefronts to the photographic plate. Fig. 2 shows a suitable optical system using a pair of master lenses. As before the two beams are incident on the plate at a slight angle to one another so that the reconstructed beams can be separated.

When a reconstruction is made by illuminating the hologram with a wavefront of finite curvature, two point sources are still reconstructed (one virtual and one real), but this time they are not symmetrically located on either side of the hologram. Their exact position depends on the location of the centre of curvature of the illuminating wavefront according to the foregoing principle.

**Comparison with other optical elements.** It is interesting to compare point holograms with Fresnel zone plates, because although the latter have never found much practical application in optical systems, their principle is somewhat similar. Zone plates, of course, were drawn by hand or machine and the production of a zone plate of the dimensions specified here with the detail required near the periphery is unthinkable. Apart from practical considerations, however, the photographic recording of point holograms is rather more than a simple method of making large zone plates. Thus if the photographic plate used for the hologram reproduces the intensity distributions falling on it in the manner already described, the density structure of each fringe (and each part of each fringe) must be characteristic of the two incident wavefronts. This allows, among other things, complete spatial resolution of phase detail.

In common with zone plates, point holograms can give rise to subsidiary foci. Examination of the light intensity along the optic axis does, indeed, reveal a number of

these at positions  $f/2, f/3, f/4, f/5$ , etc. This contrasts with the positions of the subsidiary foci for a zone plate, which occur at  $f/3, f/5$ , etc.<sup>9</sup> The differences between the two types of optical element and the intensities of the subsidiary foci are a function of the detailed distribution of transmission across the fringes of the hologram. If the intensities of the two wavefronts used for making a point hologram are not carefully matched as discussed, the response of the photographic emulsion will no longer be linear, resulting in "squaring-up" of the fringe structure, and giving the aberrated hologram some of the properties of a zone plate. The presence of subsidiary foci should present no practical problem as they are of relatively low intensity and their influence can easily be eliminated by using an off-axis system. Although transforming the curvature of a wavefront by diffraction rather than refraction or reflexion must always make the energy efficiency of a point hologram very much lower than that of a lens or mirror, this is offset by the availability of extremely bright, short-duration laser sources. Thus a Q-switched solid state laser in an optical system containing a few point holograms is capable of giving sufficient light to form an image (at least  $5 \text{ cm}^2$ ) on a photographic plate in 60 nsec. The efficiency is likely to improve when the technique of converting variations of density of photographic emulsions reversibly into those of phase has been fully mastered.

Point holograms differ from both lenses and mirrors on the one hand and zone plates on the other in one important practical respect. The ease of forming them suggests that it would be incomparably easier and cheaper to manufacture point holograms of large aperture than any other comparable optical elements. It can be shown that the fringe separation on a point hologram is given by

$$r_{(n+1)} - r_n \approx \left( \frac{f\lambda}{2n} \right)^{1/2}$$

where  $r_n$  is the radius of the  $n$ th (assumed  $\gg 1$ ) fringe from the centre,  $f$  is the focal length and  $\lambda$  is the wavelength of the illuminating light. Writing  $\alpha$  as the maximum emulsion resolution expressed in "fringes per centimetre", the maximum fringe radius that the emulsion can record is

$$r_{\max} \approx f\lambda\alpha$$

This corresponds with the maximum diameter of an off-axis point hologram in which the pole of the diffraction pattern falls at the edge. Table 1 shows values of  $r_{\max}$  for a number of plates based on quoted emulsion resolutions expressed in "line pairs per centimetre" and assuming a focal length of 3 m and a wavelength of  $0.63\mu$ . It can be shown that limitations imposed by lack of chromatic coherence are less stringent by at least two orders of magnitude for a stabilized helium/neon gas laser<sup>10</sup>.

Fig. 4. — · — · — ·, Optical axis;  $H_1, H_2$ , point holograms;  $O$ , object to be imaged on  $P$ ;  $P$ , photographic plate;  $S$ , position of schlieren stop for visualizing phase object. For explanation see text.

Fig. 5. *a*, Solid profile; *b*, phase object. For explanation see text.

Fig. 6. *W*, Window incorporating point hologram; *T*, test region. For explanation see text.

It will be seen that when high resolution emulsions are used, point holograms of very large aperture become possible. The point holograms are suitable for imaging either by scattered or by directed light, provided it is monochromatic and has a coherence length in wavelengths at least equal to the number of fringes on the hologram.

**Using point holograms.** To test the usefulness and quality of point holograms as optical elements, a simple,

Table 1

Plate	Resolution (line pairs cm <sup>-1</sup> ) approx.	$r_{\max}$ (cm)
Ilford 'FP4'	600	11
Ilford 'RL'	800	15
Ilford 'R 52'	1,800	34
Kodak 'V 1043 D'	10,000	189
Kodak '649 F'	10,000	189

two component, off-axis, optical system was set up. This consisted of one point hologram of focal length  $\sim -20$  cm for diverging a 2 mW multimode helium-neon gas laser beam and a second point hologram of focal length  $\sim +40$  cm (Fig. 4). The latter could be used either as a simple objective for imaging a real object on to a photographic plate (Ilford 'FP4') or, for displaying phase objects, as a "schlieren lens". In this case a knife edge or other suitable schlieren stop would be placed at *S* (Fig. 4), while the point hologram was still positioned so as to make the receptor optically conjugate with the test space. Two optical records taken with this system are shown in Fig. 5:

Fig. 5*a* is the solid profile of a screw-bolt, while a phase object (Fig. 5*b*) is exemplified by the pattern of standing sound waves developed in air between a 0.5 Mc/s transducer and a reflector plate. When a gas laser is used, extended exposure times are necessary.

In view of the possibility of producing large point holograms, one possible application is to wind-tunnels of large working sections in which the optically flat viewing windows could be made to incorporate the point holograms. A suitable optical system is shown in Fig. 6; among other advantages of this scheme is that it avoids long path lengths of the parallel beam in the laboratory. For instantaneous recording of transient phenomena the ruby laser can provide sufficient illumination. A calculation based on Fig. 5*a* shows the total energy emitted during the period of exposure to be approximately 1.2 J; this is readily available from quite a modest *Q*-switched ruby in approximately 60 nsec.

## Dehydrated Lanthanum-exchanged Type Y Zeolite

by

J. V. SMITH

J. M. BENNETT

University of Chicago, Illinois

E. M. FLANIGEN

Union Carbide Corporation, Linde Division,  
Tonawanda, New York

Lanthanum atoms occupy different sites in the crystal structure of dehydrated type Y zeolite as the temperature changes, probably because of the absence of residual molecules for bonding at 725° C compared with their presence at lower temperatures.

ZEOLITES have recently been exploited as catalysts, especially in the petroleum industry<sup>1,2</sup>. One advantage they have compared with earlier amorphous or poorly crystalline aluminosilicate catalysts is that crystalline zeolites are amenable to standard techniques of X-ray diffraction; it is therefore possible to locate the atomic

positions and thus to test theories of catalytic processes, especially the electrostatic field theory<sup>3</sup>. Unfortunately the tetrahedrally co-ordinated silicon and aluminium atoms are usually in a disordered arrangement, and this, together with the great tenacity of exchangeable cations for sorbed molecules, makes interpretation difficult. Also

Numbers in parenthesis following a parameter specify the random error; last significant figure unless decimal given. B-values in parenthesis were held constant.

\* The given occupancy was assumed for calculation: note that one lanthanum is equivalent to about 6.5 oxygens or sodiums. Full occupancies are S(I) 16, U 8, and others 32.

various technical problems make it desirable to use the less certain powder methods rather than the more demanding single crystal techniques.

The aluminosilicate framework of zeolite Y is of the faujasite type<sup>4-6</sup>. The faujasite type of structure<sup>4-7</sup> consists of linked tetrahedra lying at the vertices of the zinc blende arrangement of alternating hexagonal prisms and truncated octahedra. Truncation of an octahedron leaves eight hexagonal and six square faces. Four hexagonal prisms are attached to alternating hexagonal faces. The other four hexagonal faces are left free. Four sites in *Fd3m* are partly occupied by sodium and calcium atoms<sup>4-7</sup>: all are (*xxx*); S(I), *x* = 0, centre of hexagonal prism; S(I'), *x* = 0.07, displaced about 1 Å from the centre of a hexagonal prism face towards the centre of the truncated octahedron; S(II'), *x* = 0.18, displaced over 1 Å from the centre of a free hexagonal face of the truncated octahedron towards its centre; S(II), *x* = 0.23, displaced about 1 Å from the centre of the free face towards the large pore.

Infra-red absorption data obtained by Rabo *et al.*<sup>8</sup> on cerium and calcium exchanged zeolite Y have indicated strong retention of OH bonding even after vacuum activation at 500° C: elimination of the OH stretching frequency occurred only after activation near 700° C. Electron spin resonance for manganese (II) ion exchanged type X zeolite has indicated<sup>9</sup> that the movement of cations is controlled by temperature. We have tried to determine the effect of partial and complete dehydration on the cation positions, and to determine the positions of cations at various temperatures and under various environments.

X-ray powder data for lanthanum exchanged type Y zeolite were collected with copper radiation on a diffractometer. After the hydrated zeolite had been examined under ambient conditions, it was studied at room temperature in a stream of dry helium after vacuum activation at 350° C. Although the patterns are quite similar, the differences indicate structural changes. Subsequently another sample was examined in a furnace with controlled atmosphere. X-ray measurements were made directly at temperatures up to 725° C using dry helium, dry carbon dioxide and ordinary and humid air pulled through the system by a roughing pump which operated at about 100 μ pressure. The helium and carbon dioxide were dried by passing through a liquid nitrogen trap followed by an activated Type 4A zeolite trap. The X-ray patterns depend more on the temperature of examination than on the previous treatment and the gaseous environment (Fig. 1). Small differences at a given temperature in the ratio of the integrated intensities for the (311) and (533) reflexions, however, suggest that the structural details depend on the gaseous environment, and perhaps on the previous history. Metastable equilibrium apparently was reached for each measurement.

A detailed refinement was made of two patterns, one obtained from a sample under dry helium at room temperature after activation at 350° C, and one obtained directly at 725° C under helium. Broadening in the latter

seriously reduced the number of distinguishable peaks and interpretation of both suffered from superposition of diffractions. Refinement was made by least squares iteration in which the observed intensity of combined diffractions was split according to calculated amplitudes. The calculations were checked by difference Fourier syntheses. Because structure models with atoms in (*xxx*) give, for many reflexions, similar amplitudes to models which have atoms inverted through (0.125 0.125 0.125), we tested inverted models. Table 1 shows the final atomic co-ordinates. Chemical analysis gave: SiO<sub>2</sub>, 43.6; Al<sub>2</sub>O<sub>3</sub>, 14.9; La<sub>2</sub>O<sub>3</sub>, 14.0; Na<sub>2</sub>O, 2.2; loss on ignition, 25.7; total, 100.4 wt. per cent. Calculated to 192 T atoms, the cell contents are Na<sub>13.4</sub> La<sub>16.3</sub> Al<sub>15</sub> Si<sub>127</sub> O<sub>383</sub> (H<sub>2</sub>O)<sub>270</sub>. The analysis deviates from the condition, Al = Na + 3La and O = 384. The presence of some (LaOH)<sup>2+</sup> could account for the deviation, and is consistent with the low temperature X-ray results from which the presence of a bridging species such as hydroxyl between lanthanum ions is indicated. Recalculation on this basis gives an approximate distribution of lanthanum species in the unit cell of La<sup>3+</sup>(LaOH)<sup>2+</sup><sub>7.3</sub>. Because of the presence of both lanthanum and sodium, assignment of electron density is ambiguous; however, the greater number of orbital electrons in lanthanum (assumed to be 6.5 times greater than in sodium) restricts the possible atomic assignments. Interatomic distances (Table 2) were used in association with possible occupancies (Table 1) to deduce the more likely assignments. Table 3 shows the observed and calculated structure amplitudes for the unique reflexions. A weak (200) reflexion in the RT pattern violates the assumed space group *Fd3m*. The

Fig. 1. Ratio of integrated intensities of reflexions 311 and 533 uncorrected for geometrical factors. The accuracy is about 10–20 per cent of the intensity ratio. The numbers specify the sequence of the measurements. Note that there is some hysteresis with the first run with helium, and that subsequent runs with helium reached different states at high temperatures: these small differences are probably significant. Detailed measurements have not yet been made with carbon dioxide, water vapour and air atmospheres, though the high temperature data indicate some small changes. Perhaps some residual molecules occupy U at 725° C.

*B* values of the atoms at 725° C and of the cation sites at *RT* were fixed arbitrarily; tests showed that the refined occupancies were little affected by changes in *B*.

Fig. 2 shows a section through one truncated octahedron and two of the attached hexagonal prisms. There are four positions for each of  $S(I')$ ,  $S(II')$  and  $S(II)$  in each truncated octahedron corresponding to the four triad axes passing through the centre, which is actually the  $U$  site. For the  $RT$  structure, at least 1.7 lanthanum per truncated octahedron must go into  $S(I')$  and perhaps as many

as 2.0. When more than one  $S(I')$  per truncated octahedron is occupied by lanthanum, there must be pairs of lanthanum atoms 4.1 Å apart. It seems likely that  $U$  is occupied by residual water or hydroxyl, which bridges between the lanthanum atoms. Presence of hydroxyl was indicated from the chemical analyses.  $U$  lies 2.5 Å from  $S(I')$  and 1.9 Å from  $S(II')$ . The former is typical for La-O and Na-O while the latter is very short; however it should be noticed that the observed position of  $U$  would be largely controlled by the more abundant  $S(I')$  cations obscuring the true position of  $U$  atoms bonded to  $S(II')$  cations. The observed occupancy of  $U$  was  $2.9 \pm 0.7$  oxygen atoms or equivalent, considerably less than full occupancy of this eight fold site. If the possible errors of a refinement which uses non-unique reflexions, and the likelihood of strong positional displacements are considered, this occupancy level is not inconsistent with the expected full occupancy. The observed electron count for sites I, I' and II' is greater than expected from the chemical analysis for the sodium and lanthanum. This may be related to the presence of residual water or hydroxyl. The cation distribution probably depends strongly on the distribution of silicon and aluminium. On average, each hexagonal prism has 3.4 aluminium atoms-8.6 silicon atoms. Although there may be local order it seems doubtful that a structure which was produced by rapid crystallization, with this ratio, would have long range order. Consequently some six rings should contain one aluminium atom and others two aluminium atoms (and perhaps a few with none or three).  $S(I')$  is more likely to be occupied by lanthanum when the aluminium content of the nearby six ring is high. Similar considerations apply to  $S(II')$ .  $S(I)$  should be favoured when there are three aluminium atoms in the hexagonal prism. Adding to the complexity will be a tendency for the cations to avoid each other unless water molecules or similar species intervene. Thus one can envisage a complex distribution in which the most common pattern is two lanthanum atoms in  $S(I')$ , one water or hydroxyl in  $U$ , and sodium plus water in  $S(I)$  and  $S(II')$  furthest removed from the two occupied  $S(I')$ . If a few  $S(II')$  are occupied by lanthanum the observed distribution can be explained. Such a distribution depends critically on the identification of the occupant of  $U$  as an electro-negative species capable of bridging the occupants of  $S(I')$  and  $S(II')$ .

Because such a species should be removed at high temperatures  $U$  should become unoccupied and the cations should move further apart. This prediction is consistent with the observed atomic distribution at 725° C. The 16.3

Fig. 2. Sections through a truncated octahedron and two of the attached hexagonal prisms. For simplicity the drawings are idealized, and only some oxygens are shown. Not all sites are occupied simultaneously: see text. Only the shorter bond distances are shown. The duplicated bonds are out of the plane of the drawing.

lanthanum plus 13.4 sodium given by the chemical analysis would scatter X-rays in a similar manner to 18.3 lanthanum atoms. The observed total of 19.6 is quite satisfactory considering the possible errors, and it is not necessary to invoke occupancy by residual molecules. Because the observed electron count for each of the three sites is greater than that for all the sodium atoms, all three must contain at least some lanthanum. On average at least  $1.1 \pm 0.1$   $S(I')$  are occupied in each truncated octahedron. If this were unity, there need be no short distances between lanthanum in  $S(I')$  and no need for bridging atoms in  $U$ . Perhaps there are a few undetected atoms in  $U$ ; presumably none of these atoms is hydrogen<sup>8</sup>. In contrast to the  $RT$  structure,  $S(II')$  is unoccupied; instead  $S(II)$  is occupied. The resultant displacement into the large cavity can be interpreted as the consequence of repulsion from the lanthanum in  $S(I')$ . In  $S(II)$  a cation is partly shielded by the ring of six O(2) and O(4) atoms. Although  $S(I)$  is shielded partially from  $S(I')$  by six O(2) and O(3) the cations should tend to avoid simultaneous occupancy of  $S(I)$  and  $S(I')$ . Thus  $S(I)$  is probably only partially occupied, probably mainly by lanthanum. Whatever the exact distribution of lanthanum and sodium it seems likely that most if not all of the exchangeable cations are shielded from each other by intervening oxygen atoms.

On cooling the zeolite from 725° C to room temperature under a variety of environments the  $RT$  pattern is essentially regained although there are some minor differences in the patterns (compare the starting and finishing values for a helium environment in Fig. 1). This indicates that lanthanum atoms return to  $S(I')$  and  $S(II')$ . If a bridging species does not re-occupy  $U$ , the close approach of atoms in  $S(I')$  and  $S(II')$  is unstable from an electrostatic viewpoint, although there is the possibility of attraction between adjacent metal atoms as in "metal atom clusters"<sup>10</sup>. Further measurements are required to characterize the structure obtained on return to room temperature. Perhaps the zeolite "scavenges" a suitable atom or molecule from the external environment, or perhaps water molecules are converted to oxygen with loss of hydrogen during activation near 700° C.

Whatever the details, the lanthanum atoms should occupy different sites as the temperature is changed: this change appears continuous. At lower temperatures direct contact between lanthanum atoms and large sorbed molecules should be slight unless the sorbed molecules have a greater attractive power than the occupant of

site  $U$ . At higher temperatures, lanthanum atoms at site  $S(II)$  should be in direct contact with sorbed molecules. Although detailed calculations have not been made here, it is clear that strong electrostatic fields will occur in the zeolite pores, and, even though the exchangeable behaviour of cations will be governed by an attempt to minimize the asymmetric fields caused by the silicon/aluminium distribution, conflicting demands for minimum cation-cation repulsions will cause strong residual fields. Thus the present results do not conflict with the electrostatic field theory of catalytic activity. The present results cannot be used to test the concept of three co-ordinated aluminium (and silicon) as an activated site. It is not possible, either, to test the possibility that protons are responsible for catalytic activity.

These results are consistent with those of Barry and Lay<sup>9</sup>, who concluded from electron spin resonance spectra that in manganese (II) ion exchanged type X zeolite manganese (II) ions occupied  $S(I)$  in preference to lanthanum although the lanthanum (III) ion has a strongly ionic character and prefers a high co-ordination. They suggested that lanthanum may be stabilized in  $S(II)$  if residual water or hydroxyl is present, or if there is a high activation energy for migration of lanthanum, or if the configuration of minimum energy involves the greatest separation for lanthanum atoms. The first and third suggestions appear reasonable when modified to permit occupancy of  $S(I')$  and  $S(II')$ , when used respectively for low temperature and high temperature conditions.

We thank C. L. Angell, D. W. Breck, E. Fleischer and J. A. Rabo for helpful discussions, and L. G. Dowell for X-ray data. We also thank the Donors of the Petroleum Research Fund and Union Carbide Corporation for support.

## Palaeolithic Remains in Upper Egypt

by

FRED WENDORF

Southern Methodist University,  
Dallas, Texas

RUSHDI SAID

Department of Geology,  
University of Cairo

Excavations along the banks of the Nile have produced finds which indicate that Late Palaeolithic Upper Egypt was technologically less backward than it was thought to be.

THIS is a preliminary account of the recent discovery of numerous Palaeolithic remains in Upper Egypt along the west bank of the Nile River between Aswan and Luxor. Scholars have always held that few significant Palaeolithic sites would be found along the Nile in Egypt. It was believed that most of the Palaeolithic sites here either were buried deeply within the silts, or if they were near the

surface, then the sites were destroyed by the intensive cultivation of the silts during the past several thousand years. This belief was supported by the fact that north of Kom Ombo, near Aswan, *in situ* living sites of Palaeolithic age were unknown in the entire Nile Valley, in spite of the vast amount of archaeological work which had been done there with Pharaonic remains. Only a few scattered

finds of isolated and usually rolled artefacts have appeared<sup>1</sup>.

The desert areas beyond the Nile Valley have been more productive, especially Kharga and Fayum Oases, and limited occurrences of Palaeolithic materials have been reported by Caton-Thompson and Gardner<sup>2,3</sup>. Most of the Kom Ombo sites belong to the Sebilian industry which contained numerous technological and typological parallels with the Middle Palaeolithic, especially in the survival of the Levallois technique, although the Sebilian industry was found within silts of very late Pleistocene age<sup>4</sup>. The few isolated finds to the north of Kom Ombo, especially near Fayum, believed to be of Late Pleistocene age, were also strongly Levallois-like and contained many typological features reminiscent of the Middle Palaeolithic. These few finds gave a very distorted view of Egyptian prehistory.

Notably absent from the known Egyptian Late Palaeolithic materials were the long, narrow blades, burins and end-scrapers characteristic of the Upper Palaeolithic in Europe and the Levant. The survival of the technological and typological hallmarks of the Middle Palaeolithic, together with the absence of important features of the Upper Palaeolithic, led most scholars to assume that the Egyptian Late Palaeolithic cultures were culturally conservative, even retarded, when compared with adjacent areas<sup>5-7</sup>.

On a later time horizon, at the end of the Pleistocene when food production is believed to have begun, Egypt and the lower Nile Valley also are regarded as outside the main stream of these developments. Riverine environments, such as the Nile Valley, have been discounted as significant contributors to the origin of food production chiefly because of the persuasiveness of arguments supporting the "Hilly Flanks" concept, namely, that the domestication of wheat and barley occurred in the upland areas where the modern wild relatives of these plants grow today, and that the earliest known large permanent settlements based on food production are in the area of the "Hilly Flanks" of Iraq, Iran and Syria<sup>8</sup>.

Our work in Nubia has cast serious doubts on this general view of Nilotic conservatism<sup>9</sup>. Microlithic blade industries were discovered in Nubia which are dated by several radiocarbon samples as early as 17,000 B.C., as early as, if not earlier than, typologically and technologically equivalent industries elsewhere. Furthermore, several communities were discovered where there existed significant economic dependence on ground grains as early as 12,500 B.C., or nearly 3,000 years before the earliest dated evidence for a similar economic dependence in the "Hilly Flanks" area. It is not yet known if the grains used along the Nile were cultivated or wild; however, the significant use of grain at this time period, either wild or domestic, is of considerable importance because it is becoming increasingly evident that permanent, large settlements of several hundred individuals could be supported by the gathering of wild grain and hunting alone, and without the necessity of domestication<sup>10</sup>. Thus the discovery of the techniques for exploitation of this new source of food may be as important in the development of "primary village" society as any later domestication of plants, wherever that occurred.

Related to this problem of the emergence of economic dependence on ground grains is the extent of climatic change in Egypt during the Late Pleistocene. The modern arid environment of this area will not support any of the utilizable grains in a wild state. Consequently, an important change must have occurred for either wheat or barley or any other suitable grasses to have been abundant in central Egypt. Convincing evidence, however, was not available to support this hypothesis.

In order to clarify the problems of the Egyptian Late Palaeolithic, in particular the part which Egyptian prehistory played in the origin of food production, we under-

took a reconnaissance of the west bank of the Nile, beginning just north of Aswan, and working northward to Luxor (Fig. 1). The area was searched specifically for Late Palaeolithic sites dating from between 20,000 and 8,000 B.C., the critical time period involved. This survey was undertaken because during the just completed Nubian campaign, numerous Palaeolithic remains were found in southern Egypt where they were also believed to have been either buried or destroyed, and it seemed reasonable that a similar situation would be found farther north in central Egypt proper. We also postulated that one of the most promising areas to search for these remains would be along the west bank of the river where sand dunes and silts were known to interfinger in a complex sequence reflecting alternating periods of aggradation and recession.

During several previous seasons of field work in Nubia the history of the Nile Valley has been investigated in detail. From this work it is now clear that the Nile in its modern regime, deriving its main source of water from the highlands of East Africa and flowing northward to the Mediterranean, is a relatively modern feature. The oldest sediments of the Nile reflecting this regime lie about 30 m above the modern floodplain at Wadi Halfa, Sudan, and contain Late Palaeolithic artefacts dating from between 25 and 30 thousand years ago.

There seem to have been three main aggradational phases in the history of the Nile. The first and third are of limited interest here; however, the best preserved and widest spread of these is the second in the series, which, according to a number of radiocarbon dates<sup>11,12</sup>, began after 18,000 B.C. and lasted until 10,000 B.C. The maximum elevation of this silt accumulation amounted to some 20 m above the modern floodplain in Nubia and 8 m in Upper Egypt.

The majority of the deposits examined during the recent survey in Upper Egypt were identifiable with this phase of aggradation. Throughout most of this period the river continued to rise, thus building up a thicker bed in the floodplain; sand dunes were forming along the edge of vegetation on the west side and these dunes were washed and covered ephemerally during high floods. In one locality we counted more than twenty-five thin streaks of silt interfingering the dunes and following their slopes. During this period of silt accumulation the dunes were growing in an easterly direction, indicating that the prevailing winds at that time were westerlies, in contrast to the north-westerlies of today.

Towards the end of this aggradational phase there was a pause in the consistent accumulation of silts, and small ponds and lakes developed over the topographic lows in some dune fields back from the edge of the floodplain. At this time the dunes were no longer moving, but were stabilized with vegetation. At first the bottom of these ponds was un-aerated and the sediment was black and included organic matter, but then came an episode where the water became clear, the winds turned the water, and diatomites were deposited. An extensive diatomite field reaching a maximum thickness of 30 cm has been found in the dune fields west of Isna, in an area which is now being reclaimed. The ponds containing the diatomites eventually dried up, their surfaces were eroded, and, finally, they were covered by silts which were deposited during the last and highest phase of this episode.

The climatic implications of these diatomites are far-reaching, for they show that shortly before 10,000 B.C. an episode of cool and wet climate must have prevailed over Egypt. The nature of the diatomites is being investigated, but still no shallow ponds could stand for any length of time in Egypt except in cooler climatic conditions than those prevailing today. It is also significant that the development of the ponds and stabilization of dunes occurred during a recessional phase rather than during a period of aggradation of Nile silts. This observa-

tion suggests that the period of maximum pluvial conditions, when summer temperatures were at their lowest and local rainfall was greatly increased, does not correspond with the time of maximum accumulation of silt in the Nile Valley.

Associated with these deposits at several places were numerous, remarkably rich Late Palaeolithic sites containing several distinct industries, most of which were previously unreported from Egypt. The earliest industry occurs in the top of the lowermost silt and in the base of the dune which interfingered with the upper layers of the silt. It has a high frequency of Levallois technology, accompanied by a moderately high proportion of blades. The tools consist of partially backed long blades, numerous burins, denticulates and notches. This industry occurred at several sites north of Idfu, near Isna, and just south of Luxor. A developmental sequence is evident, the beginning of which probably dates before 20,000 B.C.

The next later assemblages occur within the lower dune. Two distinct industries are indicated. Levallois technology is absent in both, and both contain very high proportions of blades and blade tools. One of the industries has numerous backed blades together with double backed perforators. The other industry contains a high frequency of Ouchtata bladelets, plus occasional burins and denticulates. The geological position indicates an age for both assemblages of 14,000–16,000 B.C.

The next group of sites contain numerous backed micro-blades, truncations, lunates, trapezoids and end-scrapers. Some of them have high Levallois values and are similar to the Halfan industry in Nubia<sup>11,12</sup>; others are lacking in Levallois; some have numerous grinding stones, while

in others grinding stones are absent. Sites of this group occur at Wadi Kubbanayah and near Isna; they accompany a short interval of silt aggradation which is believed to date around 12,000–14,000 B.C.

There followed a short period of Nile recession during which permanent freshwater ponds developed in the areas beyond the Nile, and thick diatomite was deposited in these ponds. The ponds eventually disappeared, their deposits were eroded, and another level of silt was deposited over them. During this period of ponding followed by siltation there were at least three distinct industries in the area. Near Edfu there was a living site, with a typical Sebilian flake assemblage and a high frequency of Levallois technology. The second industry was represented in several sites near Isna which completely lacked Levallois technology, and yielded a moderate proportion of blades, together with numerous double backed perforators, denticulates, plus an occasional backed blade, burin, and end-scraper. Two fragmentary human skeletons were found with this group. The third industry present at this time also is very low in Levallois technology, is made primarily on flakes, and contains a very high frequency of end-scrapers and few denticulates, notches, side-scrapers and burins. All three of these industries are estimated to date between 10,000 and 12,000 B.C.

The most recent group of sites occurred again at Edfu and contain a flake industry with truncations, end-scrapers and grinding stones. They are dated with the recession of the upper silts, between 10,000 and 8,000 B.C.

The survey reported here has made four main contributions to our knowledge of North African prehistory. It

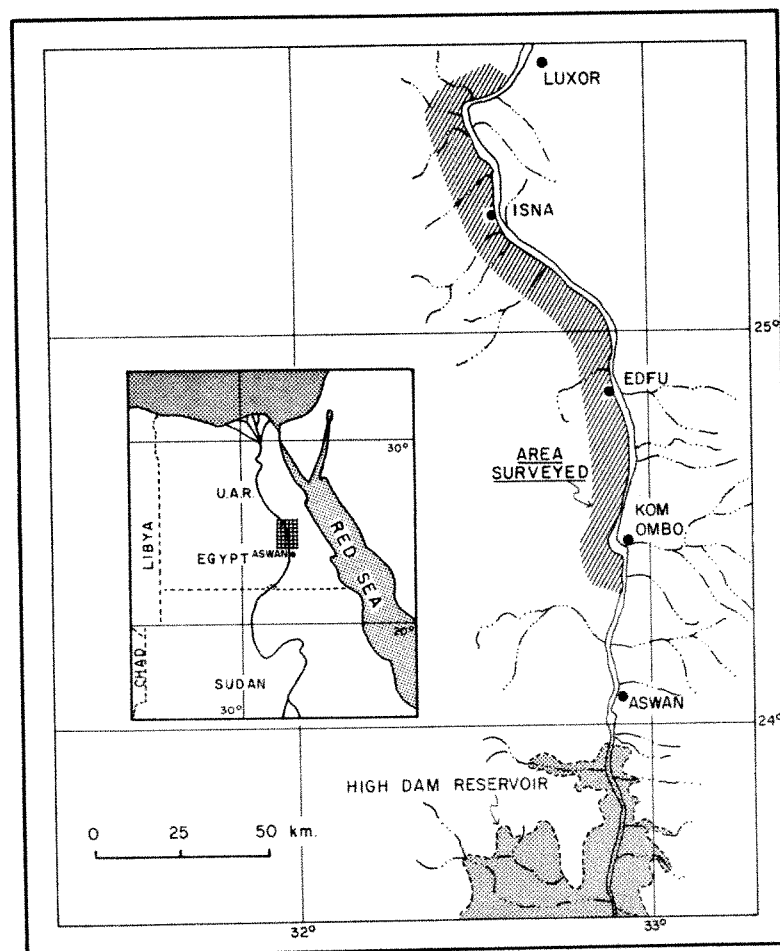

Fig. 1. Map of Upper Egypt showing area surveyed for Palaeolithic remains.

has demonstrated that: (a) Late Palaeolithic living sites do occur in Egypt in the Nile Valley; (b) the Late Palaeolithic industries from these sites are fully equivalent to the Upper Palaeolithic of the Levant and Europe in terms of developed blade technology and tool types characteristic of these areas; (c) the gathering and grinding of grain were widespread, but by no means a universal economic pursuit in Egypt during the Late Palaeolithic, apparently long before this feature appeared elsewhere; and (d) there is convincing evidence for a much cooler and wetter climate in Egypt about the time that Palaeolithic man in this area was making the first tentative steps toward the utilization of ground grain as an important source of food.

We thank Dr Bahay Issawy, Mr David Lubell, Mr James Phillips and Dr Romuld Schild for their help.

## Phyletic Evolution in Modern Birds of the Patagonian Forests

by

F. VUILLEUMIER

Department of Biology,  
University of Massachusetts-Boston,  
Boston, Massachusetts

The *Nothofagus* forests of Patagonia have been isolated from other South American forests at least since before the Pliocene, and several kinds of evidence suggest that there has been little or no opportunity for speciation among the bird populations, especially the endemic ones, within the forest region.

EVOLUTIONARY change in birds and in many other organisms is of two kinds<sup>1</sup>: multiplication of species (speciation), a phenomenon involving both time and space; and phyletic change, involving mostly time. There is always phyletic change with speciation, but phyletic change is not necessarily accompanied by speciation. Speciation is usually emphasized by neontologists because they can easily demonstrate it in living organisms, but phyletic change is more frequently emphasized by palaeontologists because fossil series often illustrate linear change very well.

Investigation of the land bird fauna inhabiting the *Nothofagus* (beech) forests of western Patagonia (southern South America) showed me that the evolutionary structure of this fauna is somewhat at variance with that of other continental faunas because of its proportionately large number of endemic taxa and the lack of presently active speciation within the forest region<sup>2</sup>. This absence of species formation is of interest because the *Nothofagus* region extends over 2,000 km along the Andes from south-central Chile to Tierra del Fuego. I think that this state of affairs is a probable consequence of the ecological uniformity and the long isolation of the *Nothofagus* forest region of South America, which have favoured phyletic evolution rather than speciation (splitting).

Parts of southern Chile and south-western Argentina are covered with *Nothofagus* forests in which one or several species of *Nothofagus* are dominant. This forest occurs from the lowlands up to timber-line, and from about 36° south to the southernmost tip of South America<sup>3,4</sup>.

The birds living in these forests are quite different, as a faunal assemblage, from those of the neighbouring steppes, as well as from those of the nearest but non-adjacent forests, those of north-western Argentina (faunal resemblances were measured on the basis of Simpson's formulae<sup>5</sup>). The *Nothofagus* forest avifauna is composed of a relatively small number of taxa: there are only about forty genera and forty-four species of land birds. Endemicity is high, however, for about twenty-two species (50 per cent) are endemic to the *Nothofagus* forest region, and especially because between five and seven of these species constitute endemic monotypic genera. Three of these monotypic genera are particularly well marked.

An analysis has revealed that the *Nothofagus* avifauna, like most faunas<sup>6</sup>, is stratified into elements of different ages and into elements of different geographical origins. There is a positive correlation between the degree of differentiation of a given taxon (species or genus) and its presumed origins in time and space. More specifically, we find that the least differentiated taxa (for example, species with a barely distinguishable sub-species in the *Nothofagus* region) are also the most widespread, in other words belonging to Mayr's<sup>7</sup> Old World and Primarily North American Families. On the other hand, the most differentiated taxa are three genera which are monotypic, well marked, and belong to an old group, the ovenbird family Furnariidae (Primarily South American Family<sup>7</sup>). They are *Sylvioorthorhynchus*, *Aphrastura*, and *Pygarrhichas*.

An investigation of the speciation potential of the species of the *Nothofagus* fauna would give information about the development of the correlation mentioned above. An analysis of speciation phenomena in the birds of the *Nothofagus* fauna<sup>2</sup> showed me that only about four species out of forty-four (10 per cent) have speciated *in situ*. That is to say these four species are the result of multiplication of species within the *Nothofagus* forest. All the other species (90 per cent) are either geographically unvariable or have very slight morphological variation of a clinal nature, and show no evidence of speciation or incipient speciation within the forest region.

A close scrutiny of the affinities of the latter species with related species elsewhere in South America revealed that in about eight cases (20 per cent) the forest species originated after a stock entered the *Nothofagus* forest, and left an isolate there. It is noteworthy that the old endemics of the *Nothofagus* forest show no more trends towards speciation than more recent endemics or than the most recent, non-endemic species.

It would seem therefore that environmental conditions in the *Nothofagus* forest region are, on the whole, quite unfavourable for the formation of species through speciation. An examination of the *Nothofagus* forest shows that it is quite uniform within and lacks barriers which would be a prerequisite for species formation, and which are found in other areas comparable in size<sup>2</sup>.

I think that the information summarized above can be explained by the following hypothesis. The *Nothofagus* region has been isolated from other forest regions elsewhere in South America so that the elements which reached the beech forests did so much like insular colonists. In other words, it is likely that only a few stocks were able to colonize the *Nothofagus* forest region, and that a high faunal turnover rate existed at all times<sup>8</sup>. (The latter aspect, however, is more highly speculative than the others, and will not be considered further here.) Those stocks which succeeded in establishing themselves in the *Nothofagus* forest encountered there conditions which did not permit further evolution by speciation (splitting), and so they diverged from their ancestors mainly in a phyletic manner.

The question which immediately comes to mind is whether there is any kind of evidence in support of the hypothesis of isolation and predominantly phyletic evolution. The history of the forest fauna obviously depends upon the history of the forest itself, and so we have to turn to botanical evidence. Today's *Nothofagus* forest is well isolated from other forest tracts in South America (Andes of north-western Argentina, lowlands of southern Brazil and north-eastern Argentina) by dry to very arid zones<sup>9</sup>. Some floral resemblances between these disjunct forests exist, but they are not important. If the forests had been connected in a recent past we would expect a much greater degree of resemblance. It thus seems likely that the *Nothofagus* forest has been isolated for a long time, but how long remains an open question. We do know, however, that *Nothofagus* has existed in southern South America since the Eocene-Oligocene (personal communication from B. Vuilleumier).

Other evidence about isolation and age comes from mammals. Two living marsupials, *Dromiciops* (an opossum) and *Rhyncholestes* (a caenolestoid)<sup>10</sup>, constitute endemic monotypic genera in the *Nothofagus* forest. They both belong to groups which have been in southern South America since the early or mid-Tertiary: the caenolestoids were present in Patagonia in the earliest Eocene<sup>11</sup>, and the microbiotheriine opossums have been there since the Oligocene-Miocene<sup>12</sup>. It seems probable that these marsupials have reached the *Nothofagus* forests during an early period when the latter forests and other South American forests were, if not directly connected, at least closer to one another than they are today (personal communication from K. F. Koopman).

These considerations suggest that, as a most conservative estimate, the *Nothofagus* forest region has been isolated at least since the Pliocene. It is more likely that it has been isolated since the Miocene, or even possibly earlier. This imprecision is unfortunate, but it must be remembered that all we have are inferences and clues, not dates, showing that isolation is real and apparently rather ancient.

The second point of the hypothesis, phyletic evolution, must now be considered. Birds are notoriously poor fossil material, and so they characteristically offer no evidence whatever about the evolutionary history of the recent *Nothofagus* bird species or genera. A series of fossil frogs, however, may permit us to draw some conclusions on this point. These frogs include *Eophractus* (Lower Eocene)<sup>13</sup>, *Calyptocephalella canqueli* (Lower Oligocene)<sup>14</sup>, and *Gigantobatrachus* (Middle Miocene)<sup>15</sup>. According to Hecht<sup>16</sup> these fossils show a probable progressive evolutionary change through time towards the modern genus *Caudi-verbera*, an isolated taxon within the Leptodactylidae. By inference, it seems possible that at least some of the isolated, monotypic endemic bird genera living in the *Nothofagus* forest today (for example, *Sylviorthorhynchus*, *Pygarrhichas*) have evolved in a similar phyletic manner.

The data on which the suggestions made in this report are based will be published in full separately. I thank the Chapman Memorial Fund, Harvard University's Evolutionary Biology Committee, and Sigma Xi for financial support, and Ernst Mayr and Beryl Vuilleumier for their advice.

After measurement of the conversion of prothrombin to thrombin in a purified system, a model has been constructed for the kinetics of the formation of prothrombin converting activity. In the model phospholipid provides a surface on to which coagulant factors bind.

In blood coagulation prothrombin is converted to thrombin as the result of the interaction of several blood coagulation factors<sup>1,2</sup>. One of the features of blood coagulation theory, which is still controversial, is the precise identity of the prothrombin converting activity. While most

authors agree that conversion of prothrombin requires the presence of activated factor X (factor X<sub>a</sub>), factor V, phospholipid and calcium ions, the form of their interaction is still in debate. Some authors suggest that the final prothrombin converting substance is a form of factor

V modified by its interaction with factor  $X_a$  (ref. 3), while others hold the view that factor V facilitates the enzyme conversion of prothrombin to thrombin by factor  $X_a$  (ref. 4). The function of the phospholipid in this system seems to depend on its providing a suitable surface on which this reaction may take place, rather than to any specific chemical constitution<sup>4</sup>.

We describe here experiments performed with purified reagents, in which the kinetics of prothrombin activation have been investigated with a view to elucidating further the nature of the process.

Bovine prothrombin was prepared and given by Dr K. Denson<sup>5</sup>. The preparation contained 10,000 NIH u/ml. of prothrombin, and less than 10 per cent of contaminating material that had neither coagulant nor inhibitory activity. Bovine factor V was prepared according to Esnouf and Jobin<sup>6</sup>; the stock solution contained 40,000 u/ml. and had no detectable contamination. Factor  $X_a$  was prepared by the conversion of factor X (ref. 7) by the coagulant protein from Russell's viper venom<sup>8</sup>, and then separating the venom protein from factor  $X_a$  by chromatography<sup>4</sup>. Factor  $X_a$  was not contaminated with any other clotting factors.

The phospholipid was a commercial preparation of mixed phospholipids, 'Inosithin'. Emulsions of this phospholipid were prepared as described by Jobin and Esnouf<sup>4</sup>.

The experiments were carried out as follows. Phospholipid, factor  $X_a$  and factor V were added together to the final concentration desired in a medium containing 12 mmolar calcium chloride and 40 mmolar *tris*-hydrochloric acid buffer, pH 7.5. The mixture thus obtained was called the "first incubation mixture". It was kept at 37° C during the "first incubation time". Except in the experiments shown in Fig. 1 where it is plotted along the abscissa, this time was always 4–6 min. After this the first incubation mixture was put in an ice bath at 0° C which prevented appreciable decay of prothrombin converting activity for at least 30 min.

To 1.8 ml. of this "first incubation mixture" 0.2 ml. of the prothrombin solution was added at zero time of the second incubation. The concentration of prothrombin in the second incubation was thus 1,000 NIH u/ml.; this concentration represents an excess of substrate for

the prothrombin activator, and did not seem to be inhibitory.

From the second incubation mixture 0.1 ml. portions were sub-sampled into 0.1 ml. of fibrinogen solution of 100 mg/ml. (human fibrinogen Kabi). The clotting time of this mixture was measured in a water bath at 37° C. The clotting times thus obtained were converted into concentrations of thrombin by comparison with the clotting times obtained by dilutions of a standard thrombin solution, in comparable conditions of pH, ionic strength, calcium ion concentration and temperature.

Fig. 2. Generation of prothrombinase activity in a mixture containing factor V, factor  $X_a$  and phospholipid. The final concentrations were 25 u/ml. of factor V, 10, 5, 2.5 or 1 u/ml. of factor  $X_a$  (as indicated), 5  $\gamma$ /ml. of phospholipid, 12 mmolar calcium chloride, and 40 mmolar *tris*-hydrochloric acid buffer, pH 7.5. The concentration of prothrombinase is expressed in arbitrary units, one unit being defined as the amount that causes a velocity of thrombin generation of 1 NIH u/10 min during the second incubation.

The amount of thrombin thus found was plotted against the incubation time in the second incubation mixture, and from this graph the initial velocity of thrombin formation induced by the prothrombin activator was estimated.

A representative experiment is shown in Fig. 1. In this experiment a mixture with high prothrombin converting activity was diluted 1 in 3 and 2 in 3, and thrombin generation has been followed in the original sample as well as in the dilutions. The two lower lines in the graph are drawn at 2/3 and 1/3 of the slope of the steepest line. It can be seen that: (a) the thrombin generation curve cannot be distinguished from a straight line in the initial phase; (b) the initial velocity of thrombin generation can be regarded as proportional to the amount of prothrombin converting activity present in the incubation mixture; (c) prothrombin converting activity tends to be unstable with larger dilutions, which can be deduced from the gradually declining slope of the thrombin generation curve at a low level of prothrombin converting activity; and (d) no lag period in thrombin formation is observed. It thus appeared acceptable to use the initial velocity of the thrombin generation curve obtained in the second incubation mixture, as a measure of prothrombin converting activity in the first incubation mixture.

Fig. 2 shows a typical curve of the generation of prothrombin converting activity in a first incubation mixture. After mixing the components there is a rapid rise of activity which very gradually falls off again. As will be seen below, the amount of prothrombin converting activity formed bears a relationship to the concentrations of factors V and  $X_a$ , and phospholipid. By varying the amounts of the reactants we have not been able to create conditions whereby the prothrombin converting activity rose slowly to a high value. If one of the clotting factors ( $X_a$  or V) was an enzyme which catalysed the conversion of the

Fig. 1. Thrombin generation in a mixture containing prothrombin and prothrombinase activity. (■—■) Thrombin generation in a mixture containing 20 u/ml. of factor V, 8 u/ml. of factor  $X_a$ , 4  $\gamma$ /ml. of phospholipid, 1,000 NIH u/ml. of prothrombin, 12 mmolar calcium chloride, and 40 mmolar *tris*-hydrochloric acid buffer, pH 7.5. (□—□) Thrombin generation in the same mixture immediately after a 2 in 3 dilution with 40 mmolar *tris*-hydrochloric acid buffer, pH 7.5 containing 12 mmolar calcium chloride. (▲—▲) The same immediately after a 1 in 3 dilution.

Fig. 3. Relation between concentration of factor V and prothrombinase activity. The inverse of the concentration of factor V expressed in  $\mu$  is plotted against the inverse of the prothrombinase activity expressed in  $\mu$ .

other to prothrombinase, then such a progressive increase in activity in certain conditions might be expected.

At relatively large concentrations (causing a velocity of thrombin formation of  $\sim 20$  NIH  $\mu$  of thrombin/ml./10 min), the half-life time of the prothrombin converting activity was estimated to be about 55 min; the half-life time of the prothrombin converting activity generated in a thrombin generation test (that is, in a system using normal plasma) was estimated to be about 10 min in the same conditions. Thus the prothrombin converting activity appeared to be more stable in its purified form than it is in plasma. This again emphasizes the point that an inhibitor of prothrombin conversion is likely to be present in plasma<sup>9</sup>.

Figs. 3, 4 and 5 show that a linear relationship between the reciprocal of the concentration of either of the reactants and the reciprocal of the final prothrombin converting activity is the simplest kind of relationship that can be deduced from these experiments. Essentially the same results were obtained when the amount of thrombin was estimated spectrophotometrically as *n*-benzoyl arginine methyl esterase activity.

This relationship cannot be accounted for by the reaction scheme of the type

or by any of its modifications. It can, however, be accounted for by a model based on the assumptions that: (a) there are a fixed number of factor  $X_a$  binding sites and a fixed number of factor V binding sites on each unit phospholipid micelle surface; (b) prothrombin conversion occurs when a factor  $X_a$  molecule and a factor V molecule, bound to the phospholipid surface, are in a favourable position one to the other; (c) binding of one of the factors does not influence the binding characteristics of the other one<sup>8</sup>. This model can be written in the following reaction formulae

The word prothrombinase refers to the complex which converts prothrombin to thrombin.

With these assumptions the following relationships will exist: (a) the concentration of prothrombinase is proportional to the number of bound factor  $X_a$  molecules/unit of phospholipid surface as well as to the amount of bound factor V molecules per unit of phospholipid surface; (b) the concentration of prothrombinase is proportional to the amount of phospholipid surface. This is written in a formula

$$C = K \cdot P \cdot \frac{P \sim X}{P} \cdot \frac{P \sim V}{P} = \frac{K}{P} \cdot P \sim X \cdot P \sim V$$

Where  $C$  is prothrombinase concentration;  $P$  is phospholipid concentration;  $P \sim X$  is phospholipid bound factor  $X_a$  concentration;  $P \sim V$  is phospholipid bound factor V concentration, and  $K$  is a constant. With the aid of elementary mathematics it can be shown

$$\text{from } P + X \xrightleftharpoons[k_{-1}]{k_{+1}} P \sim X; k_{-1}/k_{+1} = K'$$

$$\text{that } \frac{1}{P \sim X} = \frac{1}{X} + \frac{1}{P} + \frac{K'}{X \cdot P} \text{ and}$$

$$\text{from } P + V \xrightleftharpoons[k_{-2}]{k_{+2}} P \sim V; k_{-2}/k_{+2} = K''$$

$$\text{that } \frac{1}{P \sim V} = \frac{1}{V} + \frac{1}{P} + \frac{K''}{V \cdot P}$$

$$\text{So that } \frac{1}{C} = \frac{P}{K} \left( \frac{1}{X} + \frac{1}{P} + \frac{K'}{X \cdot P} \right) \cdot \left( \frac{1}{V} + \frac{1}{P} + \frac{K''}{V \cdot P} \right)$$

Fig. 4. Relation between concentration of factor  $X_a$  and prothrombinase activity. The inverse of the concentration of factor  $X_a$  expressed in  $\mu$  is plotted against the inverse of the prothrombinase activity expressed in  $\mu$ .

In these equations  $P$ ,  $X$  and  $V$  indicate the total concentrations of phospholipid, factor  $X_a$  and factor  $V$ , respectively. For the two protein factors this formula accounts for the relations found:  $1/C$  is linearly proportional to  $1/V$  at fixed  $V$  and  $P$  concentrations and linearly proportional to  $1/V$  at fixed  $X$  and  $P$  concentrations.

When the relationship between  $C$  and  $P$  is examined the formula is best written in the form

$$\frac{1}{C} = P + \frac{1}{P} (X + K') (V + K'') + (V + X + K' + K'') \frac{1}{XVK}$$

At small concentrations of phospholipid  $P$  will become negligible compared with  $\frac{1}{P} (X + K') (V + K'')$  and the formula will reduce to

$$\frac{1}{C} = \frac{1}{P} (X + K') (V + K'') + (V + X + K' + K'') \frac{1}{XVK}$$

which accounts for the relationship which we found.

At large concentrations of phospholipid the formula will reduce to

$$\frac{1}{C} = P + (V + X + K' + K'') \frac{1}{XVK}$$

which predicts the inhibiting effect of excess phospholipid that is often found.

This inhibitory action of excess phospholipid is not seen in the experiments shown in Fig. 5, because the range of phospholipid tested does not include the pertinent concentrations.

From these results it can be seen that near maximal velocity is often found at relatively small concentrations of the three reactants. This finding explains many of the reports in the literature, stating that further addition of one particular reactant did not increase the final yield of prothrombinase. The conclusion that this reactant may not therefore be a constituent of prothrombinase is apparently not justified.

Fig. 5. Relation between phospholipid and prothrombinase activity. The inverse of the phospholipid concentration expressed in  $\gamma/\text{ml.}$

The present investigations have partly been carried out under the auspices of the Netherlands Foundation for Chemical Research (SON) and with financial support from the Netherlands Organization for the Advancement of Pure Research (ZWO). We thank Mr P. P. Devilee for technical assistance.

## Changes in Visual Cortex on First Exposure of Rats to Light

It is possible that neuronal activity may produce synaptic changes, although there has so far been no direct evidence for this. Experiments with rats suggest, however, that changes in chemistry and the structure of the synapses in the visual cortex are among the consequences of the exposure of eyes to light for the first time.

### Effect on Synaptic Dimensions

It is still not clear whether synaptic changes are involved in learning<sup>1</sup>, and no functionally dependent synaptic change has been convincingly demonstrated<sup>2</sup>. It is thus reasonable to begin with the strongest possible functional

stimulus, and the first exposure of animals to light has been shown to cause changes in protein metabolism<sup>3</sup> and in the morphological development<sup>4</sup> of the visual cortex. Gyllenstein *et al.* have shown that mice reared in darkness have smaller nuclei in the cells of the upper half of the visual cortex and less internuclear material (cytoplasm

and neuropil) per nucleus. The thickness of the visual cortex is also reduced. By contrast, an increased thickness of visual cortex and increased dendritic branching have been described<sup>5</sup> in animals reared in a visually enriched environment. The first exposure of animals to light is thus a suitable stimulus to apply in looking for functionally dependent synaptic changes by electron microscopy. In the work described here particular attention has been given to the size distribution of synaptic profiles and to the density of synapses in the tissue, as well as to the qualitative appearances.

With one exception mentioned later, mother (Wistar albino) rats with their litters were kept in complete darkness from the day after birth till weaning at 3 weeks. Half of each litter was then exposed to daylight, and the rest kept in complete darkness. At biopsy, the rats were anaesthetized with pentobarbital sodium, and a pair matched for body weight and sex selected from the two groups. In later experiments, single rats with one eye covered were used, and the cortex opposite the open eye compared with that opposite the closed eye. These rats were then perfused with Pease formaldehyde fixative<sup>6</sup> and thin coronal slices of visual cortex (previously defined by retrograde degeneration)<sup>7</sup> dissected out. Each slice was cut off at the grey white boundary, and divided in half parallel to the pia. Pieces representing the upper and lower halves of the cortex were chopped into small fragments in a buffered solution of osmium tetroxide, dehydrated in acetone, block stained in uranyl acetate in acetone<sup>8</sup>, embedded in 'Araldite' epoxy resin, cut into silver sections, stained on the grid with lead citrate, and examined on a Siemens electron microscope. Fields were photographed at a fixed magnification of 14,000 regardless of their contents, and several blocks from the upper and lower halves of the visual cortex from the rat exposed to daylight and the dark-reared littermate examined. All presynaptic boutons, with or without a thickened region of apposition, were measured on photographic prints at an overall magnification of 49,000 until the diameters of about 500 profiles had been measured in blocks from each class of cortex. The latter was not identified until the measuring and counting had been completed. The number of synaptic profiles with mean diameters distributed in classes of  $0.1\mu$  was recorded. The density of the synapses in the tissue was estimated by the Abercrombie method which has previously been applied to electron microscopy<sup>9</sup>.

A rat exposed to daylight for 10 weeks after weaning differed significantly from its littermate reared in the dark: in the superficial half of the visual cortex the distribution of synaptic profiles was systematically shifted towards the larger sizes ( $0.6-1.0\mu$ ), while in the deeper half of the cortex the distribution was shifted towards the smaller sizes ( $0.4-0.1\mu$ ) compared with the dark-reared rat. The probabilities that the differences between the average diameters occurred by chance is shown in Table 1 (*t* test), together with the density of synapses in the tissue. The latter was similar in the superficial half of the cortex in the dark- and light-reared rats, but the synaptic density in the deeper half of the cortex was lower in the dark-

reared animal. This suggests that exposure to light promotes the formation of new synapses of small diameter in the deeper layers of the visual cortex, while the synapses already formed in the superficial half of the cortex grow slightly larger.

For this phenomenon to be relevant to learning one necessary condition is that synaptic changes should follow a period of exposure to light comparable in length with the consolidation time<sup>1,10</sup> (that is, something less than 1 h). The experiment was therefore repeated after shorter periods of exposure to light, as shown in Table 1. In the fifth experiment, a rat was exposed to daylight for only 3 h and then kept in the dark for 48 h before biopsy, in the expectation that processes started by the exposure to light might take longer to produce detectable morphological results. The negative result in the seventh experiment in which the biopsy was carried out immediately after exposure to light confirmed this expectation. A significant shift in the size distribution of synaptic profiles was found in each of the other pairs of rats, except in the sixth experiment. The litter used for this experiment was not put into the dark until 11 days of age (before eye opening) and it has been shown that rats react to light at this age through closed eyelids<sup>11</sup>. The synaptic dimensions and density found in this sixth experiment are compatible with both members of the pair of rats having been effectively exposed to light. In the upper half of the visual cortex, the average increase in synaptic diameter in the first five experiments was  $0.0174\mu$  (4 per cent) in the animals exposed to light, and the probability of this increase occurring by chance is less than 1 per cent (*t* test). In the lower half of the cortex, the average decrease in synaptic diameter was  $0.0634\mu$  (14 per cent) in the animals exposed to light and the probability of this increase occurring by chance is less than 2 per cent. These differences are small and can be detected only because a large number of synapses has been measured. When the minimum effective period of exposure to light has been identified a larger number of experiments must be carried out at this exposure to increase the reliability of the result. It remains to be seen how long after exposure to light biopsy should be carried out for the effect to be manifested most clearly. No qualitative difference has been noticed in the synaptic profiles, vesicles or regions of apposition between the rats reared in the light and those reared in darkness. Because the changes in synaptic size are in opposite directions in the upper and lower halves of the visual cortex, the sensitivity of the method may be increased by an exact localization in depth of the regions of maximal change. Further experiments are needed to show whether pattern vision or merely exposure to light, as suggested by the sixth experiment, is the effective stimulus. In normal animals reared in daylight, exposure to light does not generally increase the rate of neuronal firing in the visual system<sup>12</sup>, but this point does not appear to have been tested for the first exposure of dark-reared animals to light. The various effects of light exposure on the retina<sup>13</sup>, lateral geniculate nucleus<sup>14</sup> and visual cortex<sup>4,5,15</sup> of animals reared in darkness suggest that chronic deprivation of light may reduce the rate of neuronal firing

Table 1. AVERAGE SYNAPTIC DIAMETER AND DENSITY OF SYNAPSES IN THE UPPER AND LOWER HALVES OF THE VISUAL CORTEX OF PAIRS OF LITTERMATE RATS

Experiment	Time in light	Upper half of visual cortex		Density ( $\times 10^{12}/c.c.$ )	Lower half of visual cortex		Density ( $\times 10^{12}/c.c.$ )
		Average synaptic diameter ( $\mu$ )	Probability		Average synaptic diameter ( $\mu$ )	Probability	
1	10 weeks	0.439→0.456	0.01	1.28→1.19	0.493→0.397	0.001	0.847→1.35
2	2 weeks	0.417→0.445	0.05	1.50→2.07	0.500→0.435	0.01	1.25→1.43
3	1 week	0.437→0.444	0.05	1.51→1.11	0.499→0.425	0.001	0.98→1.20
4*	24 h + 48 h in dark	0.460→0.478	0.1	0.90→0.87	0.523→0.448	0.005	0.855→1.01
5*	3 h + 48 h in dark	0.363→0.380	0.02	1.88→1.81	0.394→0.387	0.1	1.40→1.50
6	4 weeks both exposed to light for 11 days	0.455→0.462	> 0.1	1.53→1.08	0.433→0.435	> 0.1	1.29→1.23
7*	3 h immediate biopsy	0.410→0.409	> 0.1	1.25→1.22	0.427→0.424	> 0.1	1.09→0.981

One rat in each pair was reared in darkness, while the other was exposed to daylight after weaning for the time shown. The figures before the arrows refer to the rats reared in the dark, and those after the arrows to the rats exposed to light. In the experiments marked with an asterisk (\*) single rats with one eye covered were used, and the figures before the arrow refer to the cortex opposite the covered eye, those after the arrow to the cortex opposite the open eye.

and that exposure of dark-reared animals to light may produce at least a temporary increase in neuronal activity.

### Effect on Incorporation of Tritiated Lysine into Protein

A VARIETY of reports has appeared indicating that the rate of protein and RNA synthesis in the nervous system is state dependent, in that it depends on the degree of stimulation of cortical or ganglionic neurones<sup>1-6</sup>. While most reports have claimed that physiological or behavioural stimulation results in increased rates of synthesis, there are apparently some conditions under which inhibition can occur (see refs. 6-8 for reviews). One strong stimulus is the first exposure to light of animals reared in the dark, which is thought to produce changes in protein metabolism in rabbit cortex<sup>5</sup>, and increased morphological development in mouse visual cortex<sup>9</sup>. Exposure to a visually enriched environment has been claimed to result in an increase in the thickness of the visual cortex and greater dendritic branching in growing rats<sup>10,11</sup>. These results suggest that the exposure of dark-reared animals to light is a suitable stimulus to apply in looking for functionally dependent changes in rates of protein synthesis. Experiments describing such changes are reported here; an accompanying article<sup>12</sup> describes some changes in synaptic size and density observed under similar conditions.

Littermate Wistar rats were placed, with the mother, within a day of birth, in cages enclosed within light-tight boxes, the boxes being opened later, when necessary, using a photographic safety lamp as the source of light. The mother was removed at weaning and the litter remained until about 50 days of age. The rats were then divided into two groups; one group was returned, in a new cage, into the light-tight boxes, the other group was placed in a fresh cage in the open laboratory under conditions of normal illumination from fluorescent ceiling lights and windows (average illumination 25 ft.-candles). The light-tight box containing the control group was placed by the side of the experimental group during the entire period of illumination, so that random factors of extraneous sounds and changes in ambient temperature affected both groups

similarly. After varying periods of continuous exposure to light, and three hours before they were killed, each animal was injected intraperitoneally with 1.0 ml. of a solution containing 50  $\mu$ c. of generally labelled tritiated lysine, specific activity 50  $\mu$ c./mmole, in 0.9 per cent sodium chloride. The efficacy of this injection route is well established<sup>13</sup>. Control animals were returned to the light-tight box, experimental animals to their illuminated cage. No food or water was provided during this final period.

Three hours after injection the animals were killed and samples of visual and motor cortex rapidly removed, using a plastic mould with appropriate holes cut out for the dissection. The samples from each hemisphere were treated separately; thus four samples were obtained from each brain. Duplicate control samples were taken from the liver at the same time. Each tissue sample was homogenized in 0.32 molar sucrose, and portions were assayed for protein<sup>13</sup>, total radioactivity, and radioactivity bound to a thrice-washed precipitate insoluble in trichloroacetic acid (TCA). Radioactive samples were dissolved in hyamine and counted in a scintillation counter.

The results were calculated in two ways. (a) By expressing the counts found in TCA insoluble fraction as a percentage of the total counts in the sample; this represented the relative specific activity (RSA) of bound to pool lysine. Three hours after injection, some 50 per cent of the total counts found were in the fraction insoluble in TCA in the brain, and a rather higher percentage in the liver. (b) A second method of calculation was to relate the counts incorporated into bound material to total protein, corrected for variation in dose/body weight. This represented specific activity. The first method, which avoids limitations due to variations in dose, injection technique or permeability of the blood-brain barrier between different animals, gave better reproducibility in a control experiment. With ten animals the standard error of the mean was better than  $\pm 5$  per cent. Data based on this method of calculation are presented here, though either method gave essentially similar results. All tests of significance were made using Student's *t* test.

Control experiments, to check whether dark confinement of the kind described above impaired vision, were made by testing animals kept for up to 50 days in the dark in a visual cliff device<sup>14</sup>. Such animals were found to respond as well as normals on the apparatus within 15 min of first exposure to light. Continuous subsequent exposure for periods of 4 days or more to fluorescent lighting did, however, produce some impairment in response. In none of the experiments to be described were the animals exposed to continuous light for more than 4 days.

Table 1. INCORPORATION OF RADIOACTIVITY INTO TCA-INSOLUBLE MATERIAL AFTER 3 H EXPOSURE OF LITTERMATE RATS TO LIGHT. NUMBER OF DETERMINATIONS IN PARENTHESES

Region	RSA		P
	Light (8)	Dark controls (8)	
Visual cortex	51.6 $\pm$ 0.6	44.8 $\pm$ 1.8	< 0.01
Motor cortex	43.6 $\pm$ 2.0	50.8 $\pm$ 2.4	< 0.01
Liver	67.8 $\pm$ 2.4	69.2 $\pm$ 1.8	n.s.

The results of one experiment in this series are shown in Table 1. After a three hour period the relative specific activity of the visual cortex of the animals exposed to light was increased by 15 per cent over the dark controls, the RSA of the motor cortex was decreased by 14 per cent and that of the liver by 5 per cent. The increase in RSA in the visual cortex, and the decrease in RSA in the motor cortex, were significant ( $P < 0.01$ ). In four experiments, in each of which eight to ten animals were used, essentially the same results were obtained for the visual cortex; in each case the RSA was increased above the control by at least 15 per cent, even though slight procedural variations in individual experiments resulted in a range of RSA values of the control litter of from 41.1 to 52.0. In each experiment the liver showed no significant difference from controls. The increase in incorporation of lysine into acid insoluble material following 3 h light stimulation

Fig. 1. Effect of exposure to light on incorporation of tritiated lysine into TCA-insoluble material in brain and liver of the rat *in vivo*. Rats were reared for 50 days in darkness and then brought into the light for varying periods of time before injection with labelled lysine and treatment as described in the text. The difference in relative specific activity between experimental and dark-control animals was calculated as described in the text. Each point represents the mean results of an experiment with at least eight littermate animals. ●—●, Visual cortex; ○—○, motor cortex; □—□, liver.

thus appeared to be confined to the visual region of the cortex (in one of the four experiments done at this time interval the motor cortex also showed a significant increase in RSA).

When light stimulation was prolonged beyond the 3 h period, however, a depression, rather than a stimulation, of incorporation resulted. These experiments are shown in Fig. 1, which shows the effects found after 1.5, 3, 12, 24, 48 and 99 h of exposure to light. Each experimental point represents the results obtained with a litter of at least eight animals; the graph is plotted by expressing the results as RSA of experimental animals as a percentage of that of controls. After 1.5 h of exposure to light there was no effect on the visual cortex, while the RSA in the motor cortex was already depressed by some 23 per cent. After 3 h the stimulation in the visual, and depression in the motor cortex, was visible, while after 12 h or more of light exposure the incorporation in both the visual and motor cortices was depressed. The greatest depression occurred at about 24 h of light exposure, when it amounted to 30 per cent. After this time, incorporation appeared to rise slowly back to the control level once more, and after 99 h of light exposure RSA in both experimental and control animals was the same. At no time during these experiments did the RSA in the liver alter significantly from control levels.

This clear, reproducible and statistically significant biphasic curve prompted several further questions. (i) Was there some permanent difference in ability to incorporate lysine between animals reared in the dark and those subject all their life to a normal animal house cycle of 12 h light/12 h darkness? Table 2 shows that there was not. For animals which had never seen the light at all, RSA in the visual cortex, motor cortex and liver was not significantly different from that of animals kept under "normal" conditions. Thus the biphasic curve represented a transient response to new experience. (ii) To what could the effects in the motor cortex be ascribed? It might be a reasonable hypothesis that if the amount of motor activity directly influenced the rate of incorporation in the motor cortex, and there was a difference in motor activity between the animals in the dark and those exposed to light, this could account for the lowered RSA. Table 3

shows the results of an experiment in which a group of normally reared 50 day old littermates were injected with tritiated lysine and placed in an activity wheel turning at 1 rev/25 sec. After 3 h of such mild but continuous motor activity, RSA in the motor cortex was increased by some 18 per cent over controls ( $P < 0.1$ ); changes in the visual cortex and liver were not significant. Thus motor activity could apparently affect incorporation into the motor cortex.

Table 3. INCORPORATION OF RADIOACTIVITY INTO TCA-INSOLUBLE MATERIAL FOLLOWING 3 h FORCED ACTIVITY ON ROTATING WHEEL. NUMBER OF DETERMINATIONS IN PARENTHESES

Region	RSA		P
	Active (6)	Inactive (6)	
Visual cortex	69.4 ± 1.8	62.7 ± 5.3	n.s.
Motor cortex	68.0 ± 2.2	57.6 ± 5.7	< 0.1
Liver	72.7 ± 3.6	72.9 ± 1.9	n.s.

Study of the relative motor activity of a group of control animals with those of their littermates brought out into the light was made by mounting both cages (one inside its light-tight box) so that they rested on pressure transducers coupled to a chart recorder. Movement of the animals inside the cages resulted in a deflexion on the recorder. Study of 6 days continuous recording showed, somewhat unexpectedly, that not only were the total numbers of movements recorded similar for both light and dark animals after the first 6 h period (2,375 movements/day in the light, 2,706 movements/day in the dark) but that both dark and light animals maintained a very regular diurnal pattern, with little or no movement between 0800–1500 h and a much higher activity at other periods of the day. During the first 6 h the number of movements in the dark was increased by some 70 per cent compared with that in the light. Thus there was only a transient difference in the pattern of motor activity of the light-exposed compared to the control animals.

(iii) Data have hitherto been presented solely on incorporation into material insoluble in TCA. To examine further which TCA-insoluble fraction increased in labelling under the experimental conditions, the TCA precipitate in one experiment was subfractionated by extracting the lipids with ethanol and 2/1 chloroform/methanol and the nucleic acids with 10 per cent TCA at 90° C for 10 min. The residue was regarded as consisting of protein. Table 4

Table 2. INCORPORATION OF RADIOACTIVITY INTO TCA-INSOLUBLE MATERIAL IN NORMAL AND DARK-REARED RATS. NUMBER OF DETERMINATIONS IN PARENTHESES.

Region	RSA		P
	Normals (6)	Dark-reared (6)	
Visual cortex	53.3 ± 3.7	57.2 ± 2.5	n.s.
Motor cortex	54.4 ± 1.7	61.7 ± 8.5	0.1 < P < 0.2
Liver	64.8 ± 2.8	67.8 ± 3.7	n.s.

Table 4. INCORPORATION INTO VARIOUS TCA-INSOLUBLE FRACTIONS FROM VISUAL CORTEX AFTER 3 h EXPOSURE TO LIGHT. NUMBER OF DETERMINATIONS IN PARENTHESES. METHOD AS DESCRIBED IN THE TEXT

RSA of	RSA		P
	Light (6)	Dark controls (8)	
Protein	40.3 ± 3.7	33.7 ± 2.9	< 0.01
Lipid	5.5 ± 2.4	7.4 ± 3.6	n.s.
Nucleic acid	5.4 ± 1.7	0.3 ± 0.3	< 0.01

shows that after a 3 h exposure to light, increases in label associated with the protein and nucleic acid were significant ( $P < 0.01$ ); changes in the labelling of the lipid fraction were not significant. About 5 per cent of the total protein, as determined using the Lowry method<sup>13</sup>, can also be extracted into the nucleic acid fraction under these conditions, and probably consists largely of nascent protein still bound to ribosomal material; amino-acyl sRNA would also be solubilized by the use of hot TCA. Either of these two constituents could account for the labelling found in the nucleic acid fraction.

What do the observed changes actually measure? The mean half-life of at least 90 per cent of cerebral protein is 10–20 days<sup>18,19</sup>, but increased incorporation over a period of 3 h need not imply net synthesis of protein. Also, perhaps, an increase in the rate of turnover of some small rapidly labelled protein fraction might be involved. While these alternatives cannot yet be distinguished, the observations none the less throw some light on the fact that although changes in the rates of synthesis of protein and RNA have previously been reported after varying types of stimulation<sup>1–8</sup>, there has been much confusion about both the specificity and the direction of the effect. The demonstration here of a biphasic response, with a stimulation in the visual cortex, followed by an apparently non-specific depression, suggests a way of resolving some of these differences. That relatively conventional biochemical techniques can be used makes some of the quantification of results simpler than that produced by autoradiography<sup>4,6</sup>. The interpretation of the phenomenon, however, is still open to doubt. It is tempting to regard the biphasic response as the sum of two different processes, one a stimulation, one a depression. One possibility might relate this to a difference in response as between neurones and glia; a second might correlate it with the inverse synaptic changes found as between the synapses of the deeper and more superficial cortical layers reported in the accompanying article<sup>12</sup>.

Other related questions that remain unresolved include the minimum period of dark exposure necessary to produce the effects, whether the effects observed are confined to the young animals used in these experiments, or can be extended also to adults, and whether such effects can only be obtained in the extreme contrast of the light/dark

situation chosen. While the stimulation conditions used in these experiments are not strictly analogous to the learning situation, there are now many reports (see, for example, refs. 1, 8, 15–17) which argue that changed rates of synthesis of macromolecules are directly associated with learning, and it would be interesting to see whether the effects described above could be obtained also in response to such, presumably less extreme, stimuli.

It is a pleasure to record the help and co-operation of Dr B. G. Cragg, of the Anatomy Department, University College, during the course of these experiments. I thank Mr A. K. Sinha for skilled technical assistance.

## Sensitivity of Aerobic Micrococcaceae to DAQ

by

L. JEFFRIES

S. A. PRICE

MARGARET HARRIS

Walton Oaks Experimental Station,  
Vitamins, Ltd.,  
Tadworth, Surrey

The presence of small amounts of certain adhesive tapes in an incubator can give rise to marked inhibition of bacterial growth and induce the formation of small colony variants, especially of Micrococcaceae. DAQ, which is volatile, is the active agent in the tapes. Staphylococci and micrococci vary greatly in their sensitivity to DAQ—a property that may be useful as a marker for certain strains. Sensitivity to DAQ in Micrococcaceae could not be related to their quinone patterns.

SUBCULTURES of *Staphylococcus aureus*, NCTC 4163, occasionally produce variant colonies on nutrient agar. This unexpected finding was made in our early investigations when we observed colonies which were minute and translucent, with cells larger than normal and predominantly Gram-negative. The size of the variant colonies was

not increased when the concentration of carbon dioxide was raised and the minute colonies were produced only at 35°–38° C. Another culture of this strain behaved similarly. The occurrence of variants was later shown to be due to the occasional presence of adhesive masking tape on microbiological assay dishes in the incubator. Cellulose

adhesive tape was shown by Houghton and May<sup>1</sup> to contain a volatile antibacterial component, which they afterwards<sup>2</sup> identified as 2,5-di-*tert*-amyl-*p*-benzoquinone (DAQ), formed by the oxidation of the 2,5-di-*tert*-amylhydroquinone, used as an anti-oxidant in these tapes. We examined our phenomenon to see whether the same inhibitor was involved and to investigate the relative sensitivity of various bacteria.

Strains of *Staph. aureus* were found to vary markedly in their sensitivity to masking tape. Three strains, one very sensitive (NCTC 4163), one resistant and one of intermediate sensitivity, showed similar differences in sensitivity to cellulose adhesive tape, to other types of self-adhesive roll tape and also to pure DAQ (prepared by oxidation of 2,5-di-*tert*-amylhydroquinone, Santovar 4). Zinc oxide plaster strip and two brands of paper mounted adhesive label were without effect. Nutrient agar or blood agar plates, incubated at 37° C in the presence of adhesive tape, absorbed the volatile inhibitor and retained it for at least a few days during storage in the refrigerator; such plates induced variant colonies of *Staph. aureus* 4163 during subsequent incubation at 37° C in the absence of tape.

**Determination of DAQ sensitivity.** Because DAQ is volatile at 37° C the serial-dilution broth technique was found to be unsatisfactory; furthermore, the results were markedly affected by the size of the inoculum and differences in sensitivity were difficult to distinguish. The incorporation of DAQ in nutrient agar was considered but, because of the necessity to dry the agar plates before use—making it probable that DAQ would be lost by volatilization—this method was not used. We introduced the DAQ on impregnated filter paper, placed either on the dried surface of the medium or inside the lids, and then sealed the plates with 'Plasticine'. For screening the organisms were grown overnight at 37° C in liquid media and one loopful was streaked across the surface of each of three nutrient agar or blood agar plates. A strip of filter paper, 8 × 1 cm, was placed on the agar surface of each plate; two of the strips contained DAQ, 10 and 100 µg respectively, and the third was not impregnated. The plates were then sealed and incubated at 37° C overnight. Cultures of known sensitivity were included in each batch of tests. Strips impregnated with DAQ did not produce zones of inhibition; colonies over the whole plate were affected because of the distribution of volatile DAQ over the agar.

The relative sensitivity to DAQ of three strains of *Staph. aureus*, shown to differ in sensitivity by the strip method, was also determined quantitatively. Nutrient agar plates were inoculated with dilutions of overnight broth cultures by the method of Miles, Misra and Irwin<sup>3</sup>, and a circle of filter paper containing 6,000, 600 or 60 µg of DAQ was placed in each lid. The plates were sealed and incubated at 37° C overnight and the results assessed by viable counts. Lower concentrations of DAQ were tested on two of the strains of staphylococci.

**DAQ sensitivity of bacteria.** (i) *Filter paper strip method.* (Fifty-one strains.) The *Staph. aureus* strains were isolated from lesions (nineteen from humans and six from animals). The coagulase-negative staphylococci and micrococci were classified according to the scheme of Baird-Parker<sup>4</sup>.

Three sensitivity patterns could clearly be discerned by comparing the number and appearance of colonies developing on plates containing DAQ with the confluent growths on control plates (Table 1). Heavy inocula revealed a small proportion of DAQ-resistant cells in sensitive cultures after a single exposure to DAQ, these resistant cells occasionally producing a few normal sized colonies on the plates, which were discounted in the assessment.

(ii) *Quantitative determination of DAQ sensitivity of three Staph. aureus strains by viable counts.* All three concentrations of DAQ gave similar results; those obtained

with 60 µg DAQ/plate are summarized in Table 2. The colony count of W.O. 134, the resistant strain, was unaffected: the counts of the Oxford staphylococcus and strain 4163 were reduced by 180-fold and more than 20,000-fold, respectively.

Table 1. DAQ SENSITIVITY OF MICROCOCCACEAE

Group	Subgroup	DAQ sensitivity						Total strains
		No. of strains	+	No. of strains	+	No. of strains	-	
Staphylococcus 1	I ( <i>Staph. aureus</i> , coagulase + ve)	2	8	17	68	6	24	25
Staphylococcus 1	II, III, IV, VI (coagulase - ve)	0	0	5	38	8	62	13
Micrococcus 2	1-8	1	8	10	77	2	15	13
DAQ, 10 µg/plate								
DAQ, 100 µg/plate								
+ + Colonies minute and distinct.								
+ Colonies normal in appearance and reduced in numbers.								
- Growth confluent, as on control plate.								

Table 2. RELATIVE SENSITIVITY TO DAQ OF THREE *Staph. aureus* STRAINS

Strain	Lowest dilution of culture giving a countable number of colonies on DAQ plate	Number of colonies/0.02 ml. of dilution of culture	
		DAQ, 60 µg/plate	DAQ 0
NCTC 4163	10 <sup>-2</sup>	1	20,000*
<i>Staph. aureus</i> (Oxford H)	10 <sup>-3</sup>	20	3,600*
WO 134	10 <sup>-4</sup>	4	4

\* Calculated from 0.02 ml. of 10<sup>-5</sup> dilution.

With minimal concentrations of DAQ (0.06 µg/plate for strain 4163 and 0.3-0.6 µg/plate for the Oxford H strain) colonies of sensitive *Staph. aureus* were translucent and markedly reduced in size but not in numbers. With strain 4163 a high concentration (60 µg/plate) was lethal in 24 h at 37° C, but 6 µg/plate was merely bacteriostatic.

The sensitivity of thirty-three organisms in ten other genera was also studied by the filter paper strip method. None of these organisms was markedly sensitive to DAQ, but two (*Bacillus cereus* and *Corynebacterium diphtheriae gravis*) showed intermediate sensitivity (+). *Shigella sonnei*, *Escherichia coli*, *Pseudomonas aeruginosa*, *Serratia marcescens*, *Lactobacillus arabinosus*, *Corynebacterium pyogenes*, *Bacillus pumilus* and species within the genera *Salmonella*, *Proteus*, *Klebsiella* and *Streptococcus* were resistant.

The morphology of cells of very sensitive *Staph. aureus* strains is markedly altered in the presence of DAQ, and the colonies developing range from normal opaque and pigmented to minute translucent types. Although these are unrecognizable as staphylococci, all variants are catalase-positive and revert to normal colonial and microscopic morphology if they are re-incubated or subcultured in the absence of tape. The strains of *Staph. aureus* tested varied in bacteriophage type, antibiotic sensitivity and origin; none of these properties correlated with DAQ sensitivity. Although there was considerable variation in the degree of sensitivity to DAQ within the species *Staph. aureus*, and also within the *Micrococcus* group, most strains of *Staph. aureus* and *Micrococcus* examined were more sensitive to DAQ than were the coagulase-negative staphylococci. Organisms of extreme sensitivity to DAQ were found only in the Micrococcaceae and this property may be useful as a marker. Houghton and May<sup>1</sup> found that the colony count of the majority of their strains of *Staph. aureus* was reduced by more than 90 per cent by cellulose tape in a plate test and most coagulase-negative staphylococci were relatively resistant. Later they<sup>2</sup> used agar containing a range of concentrations of DAQ and observed the lowest inhibitory concentration that would reduce the colony count more than one hundred times. Under our conditions, in which DAQ was introduced into the air space above the agar, we observed the reduction in the colony count at a single level of DAQ (60 µg/plate). As observed by May and Houghton<sup>2</sup>, a small number of

resistant cells was revealed by a single exposure to DAQ of a heavy inoculum of a sensitive *Staph. aureus* culture, but attempts to isolate such variants from unexposed populations of *Staph. aureus* were unsuccessful. Such resistant colonies were also resistant to Santovar A but, contrary to the findings of Henriksen and Gilje<sup>6</sup>, they retained their resistance on subculture.

**Use of adhesive tapes containing DAQ in bacteriology.** Houghton and May<sup>1</sup> drew attention to the danger of using cellulose tapes containing DAQ for sealing Petri dish cultures. Our work reinforces this and emphasizes the extreme sensitivity of certain staphylococci to DAQ. We found that as little as 7 in. of tape 1.25 in. wide, with its coated surface applied to a 'Perspex' sheet in a 6.6 ft.<sup>3</sup> incubator, had a significant effect on the growth of NCTC 4163.

Thomas<sup>7</sup> used cellulose roll tapes and tacky labels on mounts for sampling the skin flora. We deposited broth cultures of *Staph. aureus*, 4163, on polystyrene and on glass surfaces, dried them and then sampled with a brand of cellulose adhesive tape (shown to be inhibitory to this strain), and also with 'Tickotab' (J. Goshon and Co., Ltd., London, W.8) labels (shown to be non-inhibitory). The tapes or labels were then used for the inoculation of agar plates. From the glass surface, more staphylococci were isolated with cellulose tape than with 'Tickotabs', whether tested immediately after taking the impressions, or after 2.5 h storage at room temperature (25° C). Conversely 'Tickotabs' were more effective than cellulose tape for the recovery of staphylococci from plastic surfaces. The degree of adhesiveness is clearly of considerable importance in this technique and the presence of DAQ in a film used for this purpose is unlikely to affect the results, because staphylococci recovered from impressions on tape containing DAQ in these experiments were found to be fully sensitive to DAQ. Furthermore DAQ in cellulose tape, although highly volatile at 35°–37° C, was not

sufficiently so at 19°–30° C to inhibit even our most sensitive strain of *Staph. aureus*. The use of such tapes would not therefore seem to present a hazard during transport of films, except perhaps under tropical conditions.

**Sensitivity to DAQ and vitamin K synthesis in bacteria.** May and Houghton<sup>5</sup> suggested that, because DAQ inhibited only bacteria containing vitamin K as the sole quinone, it antagonized the function of vitamin K. We found, however, that a menaphthone-requiring strain of *Fusiformis melaninogenicus*, when tested in a modification of the system described by Gibbons and Engle<sup>8</sup>, produced a similar response to menaphthone sodium bisulphite, both in the absence of DAQ and in the presence of a concentration of DAQ approximately ten times that producing a bactericidal effect on the highly sensitive *Staph. aureus*, 4163. Conversely, the activity of DAQ against strain 4163 was not antagonized by non-toxic equimolar concentrations of menaphthone sodium bisulphite, menaphthone or vitamin K<sub>1</sub>. These results do not support the view of May and Houghton<sup>5</sup>, and further evidence that sensitivity of bacteria to DAQ is unrelated to their quinone patterns is given in the article that follows this.

For supplying most of the cultures studied, together with information in considerable detail, we are most grateful to Drs A. C. Baird-Parker, M. T. Parker and S. P. Lapage. We also thank Dr Mair Thomas for helpful discussions during the early stages of the work.

Vitamins, Ltd.,  
Tadworth, Surrey

The previous article showed that sensitivity of Micrococcaceae to DAQ is probably not related to their quinone patterns. This article shows that several menaquinone patterns, possibly of taxonomic significance, may be found in Micrococcaceae. Distinct menaquinone patterns characterize certain species, notably *Staphylococcus aureus*.

WIDE variations have been found<sup>1</sup> in the sensitivity of certain Micrococcaceae to 2,5-di-*tert*-amyl-*p*-benzoquinone (DAQ). May and Houghton<sup>2</sup> suggested that DAQ might inhibit bacterial growth by interfering with the function of vitamin K, and we have therefore studied the distribution of the K<sub>2</sub> vitamins (menaquinones) in staphylococci and micrococci.

Menaquinones (MK) are commonly found in non-photosynthetic bacteria and are believed to be associated with oxidative phosphorylation<sup>3–6</sup>. Typical menaquinones have unsaturated side-chains containing from six to nine isoprene units (Fig. 1, *n* = 6–9) and their distribution has

been studied by many workers<sup>7–13</sup>. *Myco. phlei* has, however, been shown to contain an unusual menaquinone, an MK-9(H), containing one hydrogenated isoprene unit in its side-chain<sup>14–15</sup>. Scholes and King<sup>16</sup> have identified an MK-8(H) in *Corynebacterium diphtheriae*. Further

\* All values are means for the number of strains shown; the ranges are in parentheses. A further ten strains of *Staph. aureus* were examined after alkaline digestion; the MK patterns were similar to those given in the table. A further strain belonging to *Micrococcus* subgroup 5 (B-P 46) was found to yield only traces of MK-6 and MK-7, even after alkaline digestion. It was therefore not possible to determine the relative proportions of the isoprenologues in this strain.

MK figures were obtained by solvent extraction alone, except where indicated as follows:

† The bacterial mass resisted solvent extraction (values obtained by alkaline digestion).

‡ After extraction the residue was digested with alkaline and yielded either a trace of MK or none.

§ After extraction the residue was digested with alkali and yielded an appreciable amount of MK.

¶ MK-n (H) indicates a tentative identification of these compounds as MKs with partially hydrogenated side-chains (see text).

variants devoid of the 2-methyl group have been described<sup>17-18</sup>. Detailed information about the distribution of MKs in the Micrococcaceae is, however, lacking.

**Micro-organisms and cultivation.** The Micrococcaceae were classified according to the scheme of Baird-Parker<sup>19</sup>. The strains examined included the majority of those tested in the preceding article and were representative of the three degrees of sensitivity to DAQ described therein<sup>1</sup>. Twenty-eight strains of *Staphylococcus* (group 1, subgroups I-IV and VI) and twenty strains of *Micrococcus* (group 2, subgroups 2, 3 and 5-8) were stored on 'Lemco' agar slopes (Blood Agar Base, Oxoid, Ltd.) at 4° C. 'Lemco' agar plates were inoculated with peptone-water suspensions of organisms and incubated aerobically for 48 h (staphylococci at 37° C and micrococci at 30° C). The growth was collected from the surface of the agar in subdued light and placed in ethanol to remove water (about 1 g wet bacterial mass/10 ml. ethanol).

**Analytical methods.** The solid matter was allowed to settle and the supernatant liquor was decanted. Ethanol (15 ml.) containing pyrogallol (50 mg) was added to the solid and the mixture was boiled under reflux for 30 min. Water (25 ml.) was added and the combined ethanolic extracts were extracted three times with light petroleum (boiling point 40°-60° C, 25 ml.). The petroleum extract was evaporated to dryness *in vacuo*. Those bacteria found to be resistant to extraction were subjected to alkaline digestion. The bacterial mass (1 g) was boiled under reflux with a mixture of ethanol (4 ml.), pyrogallol (200 mg), and saturated aqueous solution of potassium hydroxide (2 ml.) for 30 min. After the addition of water (10 ml.) the unsaponifiable lipids were extracted with diethyl ether (3 × 25 ml.). The ether extract was washed to neutrality with water and evaporated *in vacuo*. The extracted lipids, in light petroleum solution, were chromatographed on thin layers of silica gel by the method of Horth *et al.*<sup>6</sup> to separate the crude MK fraction. This was then separated into individual MK isoprenologues by paper partition chromatography<sup>6</sup>, using 95 per cent (v/v) aqueous ethanol as developing solvent. The MK isoprenologues were identified by co-chromatography with synthetic MK markers. The individual MK bands were separately eluted with ethanol from other chromatograms run in parallel and determined spectrophotometrically by the difference in absorption at 270 nm and 285 nm (ref. 12).

$\Delta E_{1\text{cm}}^{1\%}$  values for the difference in absorption at these two wavelengths were obtained for pure specimens of MK-6, MK-7, MK-8 and MK-9 (278, 244, 238 and 222 respectively). All analytical operations, where practicable, were carried out in subdued light.

**Distribution of menaquinones in the Micrococcaceae.** All the menaquinones found in staphylococci and micrococci other than the pigmented strains in subgroups 7 and 8 were identified as MK-6, MK-7, MK-8 or MK-9, although all four isoprenologues were not present in all strains (see later). The MK patterns are shown in Table 1. The menaquinones isolated from the pigmented micrococci of subgroups 7 and 8, however, differed chromatographically from the known MKs, having  $R_F$  values of 0.275, 0.182, 0.124 and 0.086, compared with values of 0.318, 0.213, 0.143 and 0.100 found for MK-6, MK-7, MK-8 and MK-9 respectively. The ultra-violet spectra of the two series of compounds were, however, identical. The menaquinones from these micrococci were thus different from the des-methyl compounds of Baum and Dolin<sup>17</sup> and, from a calculation of their  $R_m$  values<sup>20</sup>, were tentatively identified as partially hydrogenated MKs, similar to those found in *Myc. phlei* by Gale *et al.*<sup>14</sup>. In support of this conclusion, the MKs from these micrococci could be separated from the authentic MK series by chromatography on thin layers of silica gel impregnated with silver nitrate. Ubiquinones were not found in any organism examined.

**Evaluation of analytical results.** We were unable to test directly the efficiency of extraction of the MKs from the bacteria. Of 52  $\mu\text{g}$  of MK-6 added to the ethanol used for the extraction of a 1-g sample of *Staph. aureus* (Oxford H strain)\*, however, 83 per cent was recovered. From *Staph. aureus* (Oxford H strain) only 68 per cent of the MK obtained by extraction alone could be recovered after alkaline hydrolysis. The quantitative aspects of our results are therefore to be treated with some caution, because the alkaline digestion method had to be used for a number of the organisms. On the other hand, we feel that the isoprenologue ratio found may be accepted with some confidence, because it is not likely that alkaline

\* The various strains used are identified as follows: NCTC, National Collection of Type Cultures, London; WO, Walton Oaks collection of cultures; ATCC, American Type Culture Collection, Rockville, Maryland; CCM, Czechoslovak Collection of Micro-organisms J.E. Purkyně University, Brno, Czechoslovakia; B-P, strains received from Dr A. C. Baird-Parker; C, strains received from Dr M. T. Parker, Colindale.

digestion preferentially destroys individual isoprenologues. We have found that the total MK content of a given organism sometimes varies substantially between cultures grown on different occasions. The reasons for this are still obscure. Because vitamin K forms exhibition zones in a plate test with *Fusiformis melaninogenicus*<sup>21</sup>, it is evident that at least some of the MK synthesized by Micrococcaceae grown on an agar surface is lost from the cells by diffusion into the agar. The proportion so lost may vary from one experiment to another and perhaps with different batches of medium.

*MK patterns and their correlation with systems proposed for classifying staphylococci and micrococci.* Menaquinones were detected in all the Micrococcaceae examined, but in quantities ranging from a few  $\mu\text{g}$  to more than 400  $\mu\text{g/g}$  wet weight; the highest figures were among the *Staph. aureus* strains. In strains within group I (*Staphylococcus*) of Baird-Parker's<sup>19</sup> system of classification three MK patterns were revealed. Subgroup I (*Staph. aureus*) strains were distinct and contained MK-8 as the main component, comprising about 70 per cent of the total MKs; MK-9 and MK-7 were also present in all strains. In the coagulase-negative staphylococci, comprising the remaining subgroups (except subgroup V strains, which were not available for testing), the MK pattern differed from that of subgroup I. In strains within subgroups III, IV and VI, MK-7 rather than MK-8 was the main component; subgroup II strains, however, contained similar amounts of MK-7 and MK-8.

The MK patterns of coagulase-negative variants of *Staph. aureus* would be of considerable interest, because they may form a useful addition to the list of distinguishing tests proposed by Baird-Parker<sup>19</sup>.

The second group of organisms studied, the micrococci, could be divided into two broad subgroups according to the type of MK produced. The members of subgroups 2, 3, 5 and 6, together with the two non-pigmented organisms examined in subgroup 7 (B-P 25 and B-P 26), produced normal MKs. By contrast, the yellow-pigmented strains of subgroup 7 (ATCC 9341 and the CCM strains) and the red-pigmented strain in subgroup 8 produced only MKs tentatively identified as partially hydrogenated, designated MK-n(H). The major component was MK-8(H) in all members of the yellow pigmented groups, and MK-9(H) in B-P 97. The yellow-pigmented strains were placed in group 3 by Baird-Parker<sup>22</sup>, but were later included in *Micrococcus* group 2, subgroup 7 (Baird-Parker<sup>19</sup>). MK-7 was the major component in most of the other micrococci tested, and MK-8, which was present in all the staphylococci tested, was absent from the majority of micrococci. MK-6, absent from all the staphylococci, was present in a few of the micrococci and was the only isoprenologue detected in one of the two subgroup 6 strains and in both the non-pigmented organisms of subgroup 7.

It is interesting to examine our results on the micrococci in the light of the classification proposed by Rosypal, Rosypalová and Hořejš<sup>23</sup>, who distinguished three main groups on the basis of their DNA base composition. All five of the yellow-pigmented CCM strains in Table 1 were examined by Rosypal *et al.*<sup>23</sup>, who placed them in their group 1 (guanine and cytosine (GC) content in DNA 70.8–73.3 per cent), subgroup 1a, which they regard as corresponding with subgroup 7 of Baird-Parker<sup>19</sup>, containing a variety of morphological types. Although yellow pigmentation is regarded by Rosypal *et al.*<sup>23</sup> as characteristic of strains of this subgroup, they point out that rare, non-pigmented variants do occur and indeed we found that one of their strains (CCM 266) produced not only stable yellow colonies (CCM 226) (i) but also unstable cream colonies (CCM 226) (ii), the latter giving rise to colonies with either pigment; both these variants of CCM 226 produced identical patterns. The GC base composition of the non-pigmented strains, B-P 25 and B-P 26, is not known and hence their position in the

classification of Rosypal *et al.*<sup>23</sup> is not clear, but Baird-Parker<sup>19</sup> asserted that some 18 per cent of the subgroup 7 strains he studied were non-pigmented. The organisms studied by Rosypal *et al.*<sup>23</sup> consist mainly of yellow- and pink-pigmented strains, however. Strains of subgroup 1b of Rosypal *et al.*<sup>23</sup> (of similar GC content to subgroup 1a) are differentiated by the production of pink pigment and other characters; they correspond to *Micrococcus* subgroup 8 of Baird-Parker<sup>19</sup> (*M. roseus*, Evans<sup>24</sup>). The only representative of this subgroup tested was strain B-P 97, which had a different MK pattern from the yellow strains of subgroup 1a.

The significance of MK patterns in taxonomic studies on the Micrococcaceae remains to be determined by the examination of many more strains. Our results, however, show the existence of several distinct MK patterns, one of which is characteristic of the pathogen *Staph. aureus*. The relationship between the genera *Micrococcus* and *Sarcina* is currently of interest and it has been emphasized that the genus *Sarcina* should include only the anaerobic species with fermentative metabolism<sup>25</sup>. The organism formerly referred to as *Sarcina lutea* has now been included in the genus *Micrococcus* as *M. luteus*<sup>26</sup>. These yellow-pigmented organisms can be clearly separated, on MK pattern, from the non-pigmented strains in *Micrococcus* subgroup 7, with which they were placed by Baird-Parker<sup>19</sup>.

These investigations on MKs were originally undertaken as an extension of our studies on the sensitivity of micro-organisms to DAQ. May and Houghton<sup>2</sup> suggested that in bacteria that do not synthesize ubiquinone only those producing vitamin K are sensitive to DAQ. The development of resistance to DAQ would therefore be expected to result in loss of the ability to synthesize vitamin K. A strain of *Staph. aureus* (4163), highly sensitive to DAQ, and a stable DAQ-resistant variant derived from it, produced similar amounts of total and individual MKs. Furthermore, in the bacteria listed in Table 1, there was no correlation between sensitivity to DAQ and the amount of MK synthesized by the strains.

We thank Drs A. C. Baird-Parker, M. T. Parker and S. P. Lapage for providing cultures, and Dr O. Isler, Hoffman La Roche, Basle, Switzerland, for pure samples of menaquinones. We also thank Miss Barbara Cook and Mr T. Horsburgh for skilled technical assistance.

# LETTERS TO THE EDITOR

## PLANETARY SCIENCE

### Solar Radiation at 19.0 Gc/s during the Eclipse of May 20, 1966

SINCE the early days of radio-astronomy, several solar eclipses have been studied in detail at various radio frequencies, the results being summarized in a review by Castelli and Aarons<sup>1</sup>.

As a continuation of this work, observations of solar radiation at a frequency of 19.0 Gc/s (1.58 cm wavelength) were carried out during the annular eclipse of the Sun on May 20, 1966, at a site at Lagonissi (lat. 37° 47' N., long. 23° 53' E.) near Athens, Greece, at a distance of 3 km from the centre line of the eclipse, using an aerial 0.92 m in diameter and a conventional equatorially mounted radiometer<sup>2</sup>.

The predicted times of optical first contact, maximum phase, and fourth contact for the site were 08 h 04.5 m, 09 h 31.3 m, and 11 h 04.8 m U.T. respectively, and the predicted magnitude of the eclipse was 99.99 per cent, with a 1 sec duration for the maximum phase.

Throughout the day of the eclipse the sky in the vicinity of the Sun was cloudless, the zenith atmospheric attenuation at 19 Gc/s being  $0.23 \text{ dB} \pm 0.05$ .

The measured value for the effective disk temperature  $T_e$  of the Sun, corrected for the effects of atmospheric attenuation, beam shape, feed losses and mismatch, and allowing for maximum possible errors in these, was  $T_e = 15,300^\circ \text{K} \pm 5,000^\circ \text{K}$ , corresponding to a total flux (both polarizations) of  $1,200 \pm 400$  solar flux units. This is about 25–50 per cent greater than previous measurements at other frequencies would indicate for the quiet Sun at 19 Gc/s<sup>3</sup>, but the large possible error, resulting mainly from uncertainty in the aerial gain, must be borne in mind.

Fig. 1 shows the path of the centre of the Moon across the solar disk, together with the main optical features as given on the Fraunhofer Institute solar map for the day of the eclipse.

Fig. 2 shows the radiometer output, corrected for a 1 per cent drift, assumed linear, in the zero level over the

Fig. 1. Map of the Sun for May 20, 1966, showing the path of the centre of the Moon across the solar disk, with the position of the centre marked at 15 min intervals of time, together with the main sunspot regions (D12/A1, C14, A2, D13), filaments, plages and prominences as given on the Fraunhofer Institute solar map.

Fig. 2. The observed eclipse curve, together with curves computed for uniform disks of radii  $1.02 R_\odot$  and  $1.04 R_\odot$ , where  $R_\odot$  is the radius of the optical Sun. The times of beginning (a) and end (b) of the optical eclipse are marked. The inset shows the centre of the eclipse on record expanded scales.

duration of the eclipse, together with curves computed for a uniform distribution of radiation across disks of radii  $1.02 R_\odot$  and  $1.04 R_\odot$ , where  $R_\odot$  is the optical radius of the Sun. Although four sunspot regions were present (Fig. 1), and although sudden changes appeared on records at lower frequencies<sup>4,5</sup> (Anastassiades, unpublished report, Univ. Athens, 1966), it can be seen that the eclipse curve at 19 Gc/s nowhere differs by more than about 2 per cent from the  $1.02 R_\odot$  curve, and that there are no pronounced sudden changes in slope significantly greater than those of the general background noise on the curve, such as might be expected if the Moon occulted localized sources of high intensity within the solar disk. There is, however, a delay of 0.75–1 min in the observed time of minimum radio flux, which, as the eclipse was almost total, suggests the existence of a source of enhanced radiation extending to at least 11,000 km beyond the east limb. That this shift is genuine, and not due to random noise, is shown by the fact that during the first half of the eclipse the observed curve lies consistently above the calculated ones, whereas for the second half they are nearly coincident. It also appears more prominently on records made at lower frequencies<sup>4,5</sup>. Moreover, by replotting the eclipse curve against the angular separation of the solar and lunar centres and superimposing the two halves of the curve, there is seen to be a near-constant difference of 2.5 per cent between them, and if this is assumed to be due mainly to one localized source, its intensity is about  $1.3 \pm 0.2$  per cent of the total solar flux. It must be remembered, however, that this particular source was detected because of its effect on the time of minimum received radio flux, resulting from its position on the limb, and that if it had existed within the optical disk, as did the other sources detected at the lower frequencies, it would have produced a less noticeable effect on the record, and might even have remained undetected.

The radio flux minimum occurred at the time when the optical prominence P (Fig. 1) had just been covered by the Moon's limb, at the start of the second half of the eclipse, and it is therefore likely that there is a connexion between the two phenomena. Corresponding to the effect produced by the covering of this source, there should be another distortion of the record immediately prior to the optical fourth contact at the end of the eclipse. Assuming that the radio source has roughly the same shape as the prominence P, however, Fig. 3 shows that, due to the difference in geometry between the leading occulting edge of the Moon and the trailing uncovering edge, the source P would be covered in a relatively short period of time, producing a sudden change on the record

Fig. 3. Illustration of the difference between the geometries of the covering and uncovering of the east-limb prominence  $P$ .  $M1$ ,  $M2$ , position of lunar centre at times of covering, and uncovering, respectively;  $S$ , solar centre.

(the shift in time of the maximum phase), but would be uncovered much more gradually, producing a much smaller, but more prolonged, distortion in the record. Because the uncovering occurred right at the end of the eclipse its effect on the records is therefore difficult to pick out from other effects due to the Sun having drifted slightly from the centre of the beam, and to the Moon moving out towards the edge of the beam.

The total residual at the maximum phase of the eclipse was 6.2 per cent, of which about one-third was contributed by the Moon<sup>6</sup>, leaving a 4.2 per cent residual originating in the uneclipsed portion, compared with the 7.3 per cent observed by Castelli and Straka at 8.8 Gc/s<sup>4</sup>. For a uniform distribution of noise across the disk this would correspond to a radio radius of the Sun of  $1.020 R_0$ , or a maximum effective emission height of 14,000 km above the photosphere. Bearing in mind, however, that 1.3 per cent of the total radiation probably came from one localized disturbed region on the limb, these figures become 2.9 per cent,  $1.014 R_0$  and 10,000 km, respectively.

The time of first contact for the radio Sun was difficult to measure from the record with any degree of accuracy, but allowing for the fact that even with the idealized curves the initial rate of decrease in signal is very small, it appears to be between 0.5 and 1.5 min before first optical contact, corresponding to a radio radius between 1.005 and  $1.016 R_0$  (3,500–11,000 km above the photosphere). The corresponding difference for the fourth contact was masked by the effects described earlier.

This work was carried out as part of the programme of the Science Research Council's Radio and Space Research Station. We thank Professor M. Anastassiades and the staff of the Ionospheric Institute of Athens for their organization of the general eclipse programme. We also thank the manager of the Lagonissi Hotel, Athens, for permission to operate the equipment in the hotel.

## Changes of the Earth's Magnetic Field and Radiocarbon Dating

THE radiocarbon method of dating depends on several assumptions which could not have been easily verified around 1950. Two of them seem to be of considerable importance, namely, the constant rate of the mixing of deep and surface ocean waters and the constancy of the Earth's magnetic field. This communication deals with the latter assumption.

It is well known that the radioactive isotope carbon-14 originates in the upper layers of the atmosphere as a consequence of the action of cosmic rays. Their flux as well as the rate of production of carbon-14 depends on the intensity of the Earth's magnetic field. In general, a decrease in the intensity of the field causes an increase of the cosmic ray flux and also an increase in the production of carbon-14. Higher values of the field have the opposite effect. These facts have been verified experimentally.

Fig. 1. Archaeomagnetic curves for France (1), the Soviet Union (2), Japan (3) and Czechoslovakia (4).

When Libby discovered the radiocarbon method of dating<sup>1,2</sup> there were no reliable methods for investigating changes in the Earth's magnetic field. It was only by means of the double heating method of E. and O. Thellier<sup>3</sup> that it became possible to investigate the intensity of the Earth's magnetic field in the remote past by measuring the remanent magnetization of burnt archaeological objects<sup>4,5</sup>. Samples from Czechoslovakia and Turkey<sup>6,7</sup>, and a number of other countries, were measured and it was found that the intensity over the past 8,500 years varied from a half to one and a half times the present value (Fig. 1). Because of this finding it was realized that the assumption concerning the intensity of the Earth's magnetic field was incorrect.

It has been shown<sup>8</sup> that the rate of production of carbon-14 can be determined from the equation

$$P(t) = \frac{C_2}{M(t)}$$

where  $C_2$  is constant and  $M(t)$  is a function representing the change of the Earth's magnetic field with time. If we substitute experimentally determined values for  $M(t)$  and solve the differential equation

$$\frac{dI}{dt} = A \exp(-\lambda_1 t) + B \frac{2.6}{\lambda_1} - C \frac{1.2 \lambda_1}{\lambda_1^2 + \left(\frac{2\pi}{8000}\right)^2} \sin \frac{2\pi}{8000} t + D \frac{1.2 \frac{2\pi}{8000}}{\lambda_1^2 + \left(\frac{2\pi}{8000}\right)^2} \cos \frac{2\pi}{8000} t$$

we obtain

$$I_t = 15.02 \lambda_1 t + 0.548 - 0.327 \sin \frac{2\pi}{8000} t - 0.106 \cos \frac{2\pi}{8000} t$$

Fig. 2. Decay curves—according to W. Libby (I), with the influence of the Earth's magnetic field changes (II).

This represents the influence of the Earth's magnetic field on the temporal changes of the radioactivity of carbon-14. On the basis of this equation it is possible to investigate the course of the new decay curve given in Fig. 2 (full line) together with the known W. Libby's curve (dashed line). In Fig. 2 the horizontal distance between the full and dashed line shows the value of deviation of the radiocarbon dates from the historical ones.

Such deviations were empirically determined by measuring the radioactivity of samples the age of which could be ascertained by historical chronology and dendrochronology<sup>9</sup> (Figs. 3 and 4). The good agreement of the computed deviations with those ascertained empirically is only partly influenced by the fact that some of the constants in our equation must have been computed by substituting certain empirical values.

Table 1

	Short chronology based on archae- ological syn- chronizations (before 1950)	Uncorrected radiocarbon chronology	Radiocarbon chronology cor- rected by the factor of the magnetic field
Central-European early Neolithic (early phase Linear Pottery Culture)	2600 B.C.	4500 B.C.	Approx. 5000 B.C.
Early Chalcolithic of Central Europe (early TRB Culture)	2100 B.C.	3250 B.C.	Approx. 4000 B.C.
Middle Chalcolithic of Central Europe (classical phase Baden Culture)	2000 B.C.	2600 B.C.	Approx. 3300 B.C.

It can be seen from the shape of the curves (Fig. 2) that after zero (historical chronology) the difference between both curves represents about +30 years, around 2000 B.C. it is -400 years, around 4000 B.C. about -750 years. Then both curves approach each other again and they coincide shortly before zero and after A.D. 1000. Fig. 5 also reveals the mutual differences, the line labelled *a* (for the half-life of 5,568 years) is taken as a basis, and the line *b* represents the deviations for the half-life of 5,730 years. The curve *c* defines graphically smoothed deviations of radiocarbon dates from those based on dendrochronological investigations (compare Fig. 4), and curve *d* represents deviations (in years) between carbon-14 dates and historical dates. Finally, curve *e* includes the kind of deviations that are to be expected when the influence of the Earth's magnetic field is considered.

The agreement of curves *c* and *e* is quite evident, while curve *d* displays systematic deviations of +100 years; this may be explained by the fact that wood (usually timber) in archaeological constructions was usually about 100 years older when used for building or other purposes. All this proves the necessity of including the influence of the changes of the Earth's magnetic field in radiocarbon dating. Because the character of the field for the past 8,500 years has been investigated in relation to the ages of archaeological objects which are often open to certain errors, and because the nature of the field has been simplified, the results are only preliminary.

It is already possible, however, to apply preliminary corrections to the dates of some archaeological periods which can be reliably ascertained by the radiocarbon method (Table 1).

Several authors have already directed attention to the systematic character of the deviations of radiocarbon dates from historical and tree-ring chronology. Before the cause of these deviations was found, however, it was not possible to use them for correcting radiocarbon

Fig. 3. Deviations between radiocarbon and historical dates. Mean values are given by the dashed line.

Fig. 4. Deviations between radiocarbon and dendrochronological dates (according to E. Ralph<sup>8</sup> and W. Libby<sup>1</sup>). — · — · — ·, Mean values.

Fig. 5. Mutual differences among the deviations: *a*, the half-life of 5,568 years; *b*, the deviations for the half-life of 5,730 years; *c*, dendrochronological deviations; *d*, deviations of historical dates; *e*, deviations when the influence of the Earth's magnetic field is considered.

chronology outside the territories in which the deviations were originally ascertained.

## Earthquakes and Associated Faulting in Central Sudan

A SERIES of earthquakes started in the central Sudan on October 9, 1966, and was reported to be continuing into April 1967. Because the earthquakes occurred in a relatively stable part of the African land mass<sup>1</sup> away from the unstable belt of the East African and Red Sea

Rift Systems, and because of the sinistral strike-slip fault movement which was associated with the strongest shock, they are of great interest.

The strongest shock occurred on October 9 and had the following parameters according to USCGS Preliminary Determination of Epicentres: time of origin, 06:48:40.3 U.T.; epicentral co-ordinates, 12.6° N., 30.8° E.; depth of hypocentre, 11 km; magnitude (*M*), 5.1.

The nearest seismograph station, at Addis Ababa, recorded the principal shocks of the series on the first day (see Table 1).

The three stronger shocks were felt with varying intensity as far as Khartoum (a distance of 380 km at a bearing of 029°). The strongest shock was accompanied by faulting and damage to property in the region of Jebel Dumbeir (Fig. 1); this is called the Jebel Dumbeir Earthquake. Its instrumental epicentre as determined by USCGS lay within 1 km of the jebel. The frequency of shocks felt in the region dropped from more than twenty in the first 24 h to fifteen per day during the second week of activity. The intensity ranged from III to V (ref. 2). At the end of December, two to six shocks per day were reported. Later reports indicate a further fall in frequency.

Jebel Dumbeir lies at the north-eastern edge of a gentle topographical swell in the central plain of the Sudan<sup>3</sup>. It rises to a height of 260 m above the surrounding country, which stands about 500 m above sea level. Jebel Ed Dair (1,413 m) lies to the south-west. The central part of the swell is occupied by the Nuba Mountains, which are a group of steep jebels with large intervening pediments and basins; they reach a maximum height of 1,460 m. To the west and north-west the swell may merge with the volcanic hills (Tertiary and Recent) of Jebel Marra (3,088 m) and Meidob.

Jebel Dumbeir and Jebel Ed Dair are composed respectively of syenitic and granitic intrusions in the Basement Complex<sup>4</sup>. The Nawa formation (Palaeozoic-Mesozoic undifferentiated) occurs in small patches within the swell and the Umm Ruwaba formation (Tertiary-Pleistocene) surrounds the swell on all sides except the north-west<sup>5,6</sup>. The Nubian Sandstone formation (late Mesozoic) occurs to the north and flanks the Umm Ruwaba formation on the west. Superficial deposits overlie the bedrock over much of the area.

Because the Umm Ruwaba formation probably lies in two sub-parallel synclines trending N.W.-S.E. (ref. 7), the swell—in so far as it forms part of the intervening anticline—assumes a tectonic significance; it may be an offshoot of the greater swell occurring at the Sudan-Chad border<sup>8</sup>.

Jebel Dumbeir and Jebel Ed Dair are part of a N.E.-S.W. trending belt of intrusions and extrusions of unknown age; the belt extends from Jebel Hagiarat south-westwards for at least 100 km. The master joints follow two predominant trends, N.E. and N.W.

Table 1*		
Time at Addis Ababa	Estimated distance	Estimated <i>M</i>
06:06:22 U.T.	1,010 km	5.0
06:50:47	1,000	5.7
07:19:(35)	1,000	4.8
10:30:30	1,075?	5.3

\* Data from P. Gouin, personal communication.

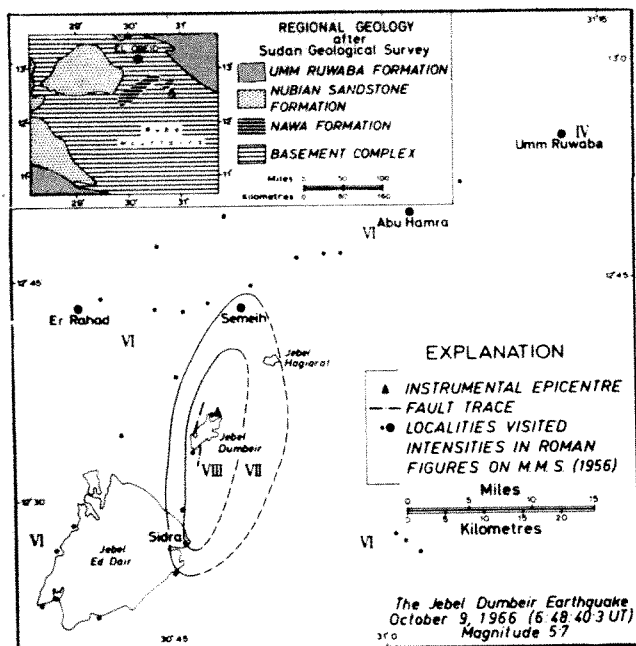

Fig. 1. Intensities and 'isoseismals' (on Modified Mercalli Scale—1956 version), and the fault trace associated with the Jebel Dumbeir Earthquake of October 9, 1966. The inset shows regional geology in the central Sudan. The epicentre of the earthquake is shown in both the maps.

The strike-slip faulting in the bedrock which took place at the time of the Jebel Dumbeir Earthquake was revealed by *en échelon* tension gashes in the overlying clayey superficial deposits (Fig. 2). North of Jebel Dumbeir the gashes formed a linear belt about 4 km long, trending about  $020^\circ$ . The gashes themselves trended at  $340^\circ$  and indicated a sinistral strike-slip movement. South of the jebel the belt swung round from an initial trend of  $343^\circ$  to a linear trend of  $012^\circ$ . High intensity shocks were felt at Semeih to the north of Jebel Dumbeir and at Sidra to the south, but it was not possible to identify or connect the gash belt with either of these areas. In all, gashes were observed for about 6 km and were not reported from anywhere outside the belt.

There was no obvious vertical displacement; because there was no linear feature crossing the belt the magnitude of horizontal displacement along the fault could not be estimated. Since the gashes showed only a little

Fig. 2. The middle part of a typical tension gash (here having a maximum width of about 4 cm) which accompanied the Jebel Dumbeir Earthquake, in ground north of the jebel.

distortion it may be assumed that the horizontal displacement was small.

The fault trace in the Jebel Dumbeir region was not so accentuated as the trace associated with the Imperial Valley Earthquake of 1940 (compare Fig. 2 with Fig. 28–12.4 in ref. 2), where the gashes were highly distorted and earth was piled up to a height of 4 ft. in a narrow belt. In contrast, the gashes associated with the Jebel Dumbeir Earthquake were long, easily recognizable and slightly distorted.

The 'isoseismals' (lines separating zones of equal intensity) for the Jebel Dumbeir Earthquake are plotted in Fig. 1 on the basis of the 1956 version of the Modified Mercalli Scale<sup>2</sup>. The intensity information in ground east and south of Jebel Dumbeir is incomplete because the area is sparsely inhabited. High intensity at Sidra is estimated on the basis of the reports of appearance of water in dry wells following the earthquake.

The 'isoseismals' show an approximate parallelism with the fault trace. Intensity appears to have been relatively higher in regions where Basement Complex formations underlie the superficial deposits than where these deposits are underlain by bedded sedimentary rocks. Consequently, El Obeid, which is underlain by Basement Complex and is situated at a distance of 90 km from the epicentre, experienced an intensity of V, while Umm Ruwaba, where a considerable thickness of the sediments of the Umm Ruwaba formation underlies the superficial deposits and which is situated at a distance of only 60 km from the epicentre, experienced an intensity of IV.

Seismological studies of the nature of sub-surface faulting show a considerable amount of strike-slip movement along faults in the African Rift Systems<sup>9–11</sup>. As a result of the analysis of two shocks (epicentres close to  $1.5^\circ$  N.,  $30.5^\circ$  E.), Sutton and Berg<sup>11</sup> deduced a component of sinistral strike-slip movement along a fault running parallel to the western wall of the Lake Albert Rift. This has not so far been supported by field evidence. A seismological study of the Jebel Dumbeir Earthquake might reveal whether the fault-plane solution accords with the surface evidence of a sinistral strike-slip movement.

The Jebel Dumbeir Earthquake is of special significance because no earthquake has been recorded the origin of which was within 700 km of its epicentre. Sieberg's and Mushketov's maps as reproduced in Gorshkov<sup>12</sup> appear to have been based on reports of earthquakes felt in the region. Instrumentally recorded shocks are confined to the south along the Western Rift and to the east along the Abyssinian and Red Sea Rift systems.

Along the Western Rift System, the earthquake epicentres for the period January 1955–March 1964 (ref. 13) show a maximum alignment along longitude  $30^\circ (\pm 1^\circ)$  E. and most of the epicentres in this belt,  $2^\circ$  wide, lie between the latitudes  $10^\circ$  S. and  $2^\circ$  N. Three epicentres lie further south, the southernmost at  $26.14^\circ$  S. Although not recorded in literature, local earthquakes have been reported frequently from Rejaf ( $4.7^\circ$  N.,  $31.5^\circ$  E.), a village in the southern Sudan<sup>14</sup>. The only earthquake recorded in this region occurred in 1915 and had the epicentral co-ordinates as  $6^\circ$  N. and  $31^\circ$  E. (ref. 1). It appears then that seismic activity associated with the Western Rift continues along longitude  $30^\circ$  E. at least as far as latitude  $6^\circ$  N. Further north along this belt, earthquakes have been reported from Dongola ( $19.1^\circ$  N.,  $30.5^\circ$  E.) (ref. 14) and from Fayum, near Cairo<sup>12</sup>. The relationship of these scattered and relatively rare events to the central active zone needs further investigation.

### Cartier Furrow, a Major Structure along the Continental Margin of North-western Australia

A COMPILATION of recent aeromagnetic surveys in offshore north-western Australia<sup>1-4</sup> (Fig. 1) reveals a furrow in the

magnetic basement, which I propose to call the Cartier Furrow, after Cartier Island. The furrow is at least 1,250 km long, and 6 km deep, and is filled with sediment. It underlies the upper continental slope except where it crosses the Londonderry Rise, which is a spur in the continental shelf. The furrow is bounded on its south-eastern side by the offshore Bonaparte Gulf Basin in the north, by the offshore Canning Basin in the south, and, in between, by a prism of non-magnetic rocks which thin south-eastward towards the Pre-Cambrian Kimberley Block. The north-western side of the furrow is marked by the atolls of the Rowley Shoals, Scott Reef, and Seringapatam Reef, which rise from the continental slope; by the outer part of the Londonderry Rise, which is crowned by the reefs of Ashmore Island, Cartier Island and Hibernia Reef; and by the south-east slope of the Timor Trough. From a comparison with onshore surveys in the Bonaparte Gulf Basin, Veevers and van Andel<sup>5</sup> identified the magnetic basement beneath the Sahul Shelf as either a layer or layers high in the Pre-Cambrian of the Kimberley Block, or Lower Cambrian volcanics. The magnetic basement in the landward part of the Canning Basin<sup>6</sup>, as shown by drill holes, is crystalline Pre-Cambrian rock (granite or metamorphics), so that the magnetic basement offshore probably coincides also with the surface of Pre-Cambrian rocks.

The increasing thickness of the non-magnetic rocks northward and westward of Dampier Land is confirmed by surveys using conventional seismographic methods<sup>7</sup>. In these offshore areas therefore the contours of the magnetic basement probably indicate the approximate

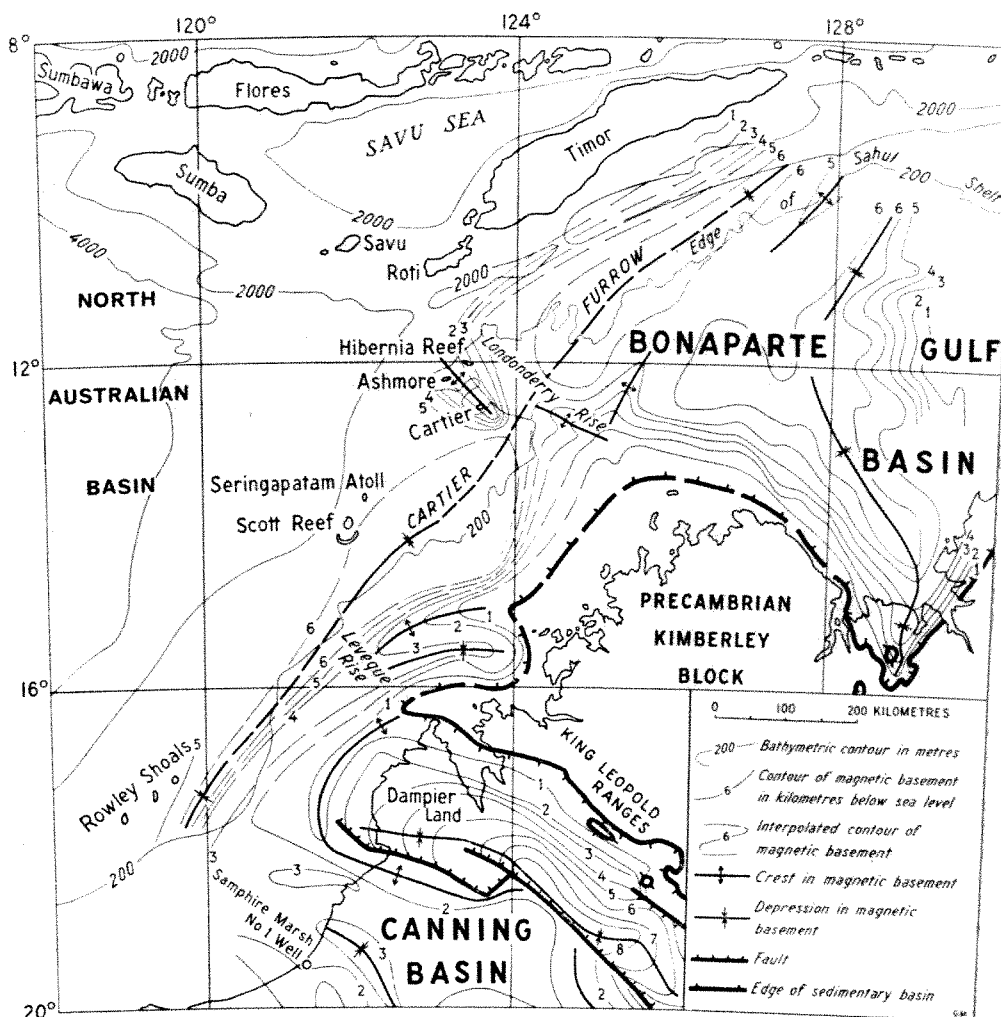

Fig. 1. North-western Australia and south-eastern Banda arcs, showing the Cartier Furrow and other structures of north-western Australia.

Fig. 2. Diagrammatic sections, with vertical scale much exaggerated, showing the development of the Cartier Furrow in the Rowley Shoals/Samphire Marsh area.

depth to the Pre-Cambrian rocks, or conversely the thickness of the overlying Phanerozoic rocks. In the Timor Trough, this relation does not hold because the Phanerozoic rocks of nearby Timor contain abundant volcanic and crystalline rocks, which are strongly magnetic.

The age within the Phanerozoic of the sediments that fill the Cartier Furrow can be determined directly only by drilling. Indirect methods indicate that the sediments are probably Mesozoic and Cainozoic. A reflexion seismograph traverse<sup>7</sup> shows that the sedimentary section thickens by some 3,000–3,500 m from near Samphire Marsh No. 1 Well on the shore of the Canning Basin to the Rowley Shoals, and that progressively younger horizons appear towards the north-west. The main reflector is the unconformity between the Permian and Middle Jurassic to Lower Cretaceous sediments in Samphire No. 1 Well<sup>6</sup>. Because the section thickens above the unconformity and progressively younger horizons appear north-westward, the thicker section includes sediments younger than Lower Cretaceous, probably reaching into the Cainozoic. In the Timor Sea area, van Andel and Veevers<sup>8,9</sup> deduced on geomorphological grounds that the shelf was exposed for a long period in the Cainozoic, and that thick sediments were deposited in front of the present shelf edge on the south-eastern slope of the Timor Trough. Except possibly for a brief marine incursion in the Miocene<sup>10</sup>, the Sahul Shelf was not covered by the sea until late in the Pleistocene. If the Rowley Shelf had a similar history during the Cainozoic, then the Cartier Furrow may be interpreted as a subsiding zone at the continental margin that was filled in the Cainozoic with sediment deposited behind the shelf edge, locally marked by fringing reefs (Fig. 2).

In the late Pleistocene, the region subsided some 120 m; the Cartier Furrow became the upper part of the present

continental slope, and those reefs that were able to grow upward by keeping pace with the subsidence became the present upper continental slope banks (Rowley Shoals, Scott Reef, Seringapatam Reef). According to this assumption, the continuation of the furrow across the Londonderry Rise indicates that the Rise originated late in the Pleistocene. The Londonderry Rise is the middle part of a north-west lineament that extends from the north-western coast of the Kimberley Block to the islands of Savu and Sumba. These islands rose in the 'Young Quaternary'<sup>11</sup>, possibly in response to the same forces that elevated the Londonderry Rise.

In his regional analysis of offshore north-western Australia in 1953, Fairbridge<sup>12</sup> pointed out that "depressions and rises in the shelf are arranged opposite the basins and swells of the continent. Their structural histories appear to be analogous". Offshore work since 1953 has shown that this arrangement is so for part of the Sahul Shelf<sup>6</sup> but not so elsewhere. By extrapolating the King Leopold Range (the King Leopold Mobile Zone of Traves<sup>13</sup>) seaward into the poorly surveyed offshore Leveque Rise, Fairbridge was misled into concluding that this rise was an area of shallow Pre-Cambrian basement overlain by a film of younger material, and concluded generally that the structural grain of the land, which runs at right angles to the continental margin, persisted seaward, thus overlooking the possibility of a longitudinal sedimentary trough along the continental margin. Teichert<sup>14</sup> had expressed this possibility in his concept of the "Westralian Geosyncline, which forms the southward continuation of the Timor-East Celebes geosyncline of the East Indies and thus represents the southern part of a continuous geosynclinal trough bordering the Australia-New Guinea Shield on the west". This concept was based chiefly on the similarity of some Permian, Jurassic and

Cretaceous faunas of north-western Australia to contemporaneous ones in Indonesia, and not, as Umbgrove<sup>15</sup> remarked, on sedimentological and structural similarities, which do not exist.

Twenty years later, Teichert<sup>16</sup> seemed to lose sight of his Westralian Geosyncline, and followed Fairbridge in drawing the major structural features of the region at right angles to the continental margin. Boutakoff<sup>17</sup>, reviving Teichert's early concept, made a novel interpretation of the bathymetric chart; he postulated several ridges along the outer edge of the shelf, and suggested that these are submerged folded ranges, the highest points of which are the base of the scattered reefs in the region. As noted by van Andel and Veevers<sup>9</sup>, "examination of the chart (Admiralty Chart 475) shows that, whatever the merit of the idea itself, the bathymetric data do not permit this conclusion". An example of Boutakoff's unacceptable contouring is pertinent here. "Whatever their origin, the Rowley Shoals, Scott Reef and Seringapatam Atoll have the morphology of atolls and they rise from the outer shelf. By disregarding contradictory soundings, Boutakoff has extended what the chart shows to be pinnacles into the crests of 'mountain ranges'". Nevertheless, Boutakoff's hypothesis that the sediments thicken in the general area of the postulated ridges is not entirely wrong. That the "ridges" contain folded strata seems to be disproved by seismographic surveys, and, more importantly, the existence of the "ridges" themselves is disallowed by the bathymetry.

Wider issues raised by the discovery of the Cartier Furrow—its relation with the Indonesian arcs and the deep floor of the Indian Ocean on the one side, and with the sedimentary basins of north-western Australia on the other—will be discussed in a more extensive paper to be published elsewhere<sup>18</sup>.

I thank Dr R. O. Brunnschweiler, Dr A. A. Öpik, Mr J. N. Casey, Mr J. E. Thompson and Mr K. A. Townley for valuable criticism of the manuscript.

## PHYSICS

### Mechanism of Radio Emission from Extensive Air Showers

THE fact that large cosmic ray air showers can generate detectable pulses of electromagnetic radiation at radio

frequencies was first established by Jelley and his collaborators at Harwell, Jodrell Bank and Dublin<sup>1,2</sup>. The pulses have been detected by several other research groups<sup>3-5</sup>, but there is as yet no clear picture of just how the radiation is produced. Theoretical treatments by Kahn and Lerehe<sup>6</sup>, Colgate (personal communication) and Allan<sup>7</sup>, all suggest that the principal mechanism should be the motion of charge due to the lateral displacement of shower particles by the Earth's magnetic field. The polarization to be expected from this geomagnetic mechanism is perpendicular both to the shower axis and to the magnetic field lines.

Alternative mechanisms can, however, be envisaged. For a shower which is not electrically neutral, but contains—as is expected—an appreciable excess of negative particles<sup>8</sup>, radiation may also occur as a result of the longitudinal motion. This pseudo-Cerenkov radiation would be polarized radially with respect to the shower axis. Two further mechanisms have been suggested recently, namely, bremsstrahlung from the delta rays associated with the shower tracks<sup>9</sup>, and acceleration of the ionization electrons in the atmospheric electric field (W. N. Charman, personal communication). These also have their characteristic polarizations; the bremsstrahlung would be unpolarized, while the polarization due to the atmospheric electric field would be typically vertical.

The experimental evidence hitherto available on polarization has been indirect and conflicting. At Jodrell Bank<sup>10</sup>, radio pulses were detected by two similar receiving channels, one directed in the general direction of the Earth's field and the other in a direction at right angles. The rate of detection in the two channels was not significantly different, a finding which disagrees with the expectations of the geomagnetic deflexion theory. On the other hand, the Moscow and Kharkov groups<sup>11</sup> state that their measurements with single antennae oriented E.-W., forming part of the large Moscow air shower array, give better internal consistency when the polarization is assumed to be that predicted by Kahn and Lerehe.

We wish to report here measurements on the amplitude and polarization of the radio pulse from an unusually large shower recorded by the Haverah Park air shower array. The direction of polarization in the horizontal plane has been unequivocally determined; as will be seen, it agrees very well with that expected from geomagnetic deflexion but disagrees with the expectations from the other mechanisms that have been mentioned.

Two receivers were used, of frequency 32 Mc/s and bandwidth 5 Mc/s. One receiver was connected to a pair of in-phase, half-wave dipoles supported  $\lambda/4$  above the ground,  $\lambda/2$  apart and oriented along the magnetic N.-S. line. The other receiver had a similar antenna system, oriented E.-W. The four dipoles made up the sides of a square. The receiver outputs were displayed on separate oscilloscopes and photographed through mirrors by a single camera whenever the Haverah Park particle array was triggered by a shower of primary energy  $\geq 10^{11}$  eV. The position on the time base (total length 10  $\mu$ sec) at which any radio pulse associated with the shower should occur could be calculated from the particle data to  $\sim 0.2$   $\mu$ sec.

It was found (contrary to our earlier experience at 60 Mc/s) that the background against which radio pulses had to be observed was very much higher than the galactic noise level. Spurious pulses with a voltage amplitude more than ten times the galactic noise appeared at frequent and erratic intervals on every time base. This made immediate visual identification of the true radio pulses difficult. Six possible candidates were selected from among 200 showers on the basis of amplitude alone, but five of these had to be rejected when checked against the timing requirement.

The sixth event was unique. Among all the pulses observed, this was much the largest, being the only one to go off the screen, and its timing in relation to the associated shower was correct to 0.2  $\mu$ sec. Because there

were only six candidates on some 4,000  $\mu\text{sec}$  of time base, there can be little doubt that this big pulse was genuinely associated with the shower. The particle analysis of the shower only strengthens this conclusion. The primary energy of  $(2^{+2}_{-1}) \times 10^{19}$  eV makes it one of the largest recorded at Haverah Park, and it is reasonable that this should be the one shower to produce a large radio pulse.

Table 1

	Relative amplitudes in N.-S. aerial	Relative amplitudes in E.-W. aerial
Geomagnetic deflexion	1.0	0.10
Radial polarization	1.0	1.85
Bremsstrahlung	1.0	0.61
Vertical polarization	1.0	2.75

The big pulse came from the pair of dipoles oriented N.-S. On the E.-W. channel the oscilloscope showed no more than the usual interference background. The relevant voltage levels at the receiver input terminals (50  $\Omega$  impedance) were about 0.5 mV for the background pulse amplitudes, 2 mV for saturation, and an estimated 5 mV for the big (off-screen) pulse. The voltage gains in the two channels did not differ by more than 10 per cent. Accordingly, we can conclude that the direction of polarization in the horizontal plane was magnetic N.-S. to a precision of about 0.1 radians or about  $5^\circ$ .

The shower which produced the radio pulse could be analysed very precisely because of the information on particle density obtained from the first of the outer (2 km) stations of the Haverah Park array to be brought into use. We are indebted to Dr R. J. O. Reid and Dr A. A. Watson of the University of Leeds for providing us with the results of their analysis. The shower, of total energy  $(2^{+2}_{-1}) \times 10^{19}$  eV, struck the ground with its axis ( $650 \pm 50$ ) m from the radio aerials at a bearing ( $25 \pm 5^\circ$ ) south of magnetic east. The zenith angle of the shower was ( $43 \pm 3^\circ$ ), and its azimuth ( $20 \pm 5^\circ$ ) south of magnetic east. The Earth's magnetic field at Leeds is directed  $9^\circ$  W. of true north, and the dip angle is  $68^\circ$ . From these figures one can calculate immediately the relative amplitudes to be expected from the N.-S. and E.-W. aerial systems for each of the four mechanisms mentioned above (Table 1).

It is clear from Table 1 that the experimental observations are decisively in favour of geomagnetic deflexion.

A further topic on which useful conclusions can be drawn is the dependence of radio pulse amplitude on total shower energy. The big pulse was obtained with an effective aerial aperture of about 50 m<sup>2</sup> and the receiver bandwidth was about 5 Mc/s at a centre frequency of 32 Mc/s. The received power level was thus  $10^{-6}$  W and, with a pulse length of 0.2  $\mu\text{sec}$ , the total energy was  $\sim 2 \times 10^{-13}$  J. In our earlier experiments at Haverah Park<sup>3</sup>, we used an aerial array of area about 100 m<sup>2</sup> and a receiver bandwidth of 2 Mc/s centred at 60 Mc/s. The increased aerial area partially offsets the effects of reduced bandwidth, and the overall sensitivity was less than in our present experiment by a factor of about 2. At 60 Mc/s we identified a number of radio pulses of amplitude two or three times the galactic noise level, from showers of primary energy a few times  $10^{17}$  eV. Only about 5 per cent of such showers gave detectable pulses, and we infer that the necessary coherence is only obtained at 60 Mc/s when there is a favourable fluctuation in the longitudinal development of the shower. Assuming that the maximum pulse amplitudes observed correspond to effectively full coherence, we may assert that showers of energy a few times  $10^{17}$  eV give pulses at about 50  $\mu\text{V}$ , and that showers of energy a few times  $10^{19}$  eV give pulses at about 5 mV at similar distances from the shower axis. The ratio of the pulse amplitudes is thus of the same order as the ratio of the primary energies, and the observations support the theoretical expectations that the pulse amplitude should be proportional to primary energy.

We thank all our colleagues at Haverah Park for their co-operation during the present experiment. Mr D. Pearce gave valuable assistance in the building of the aerial array and in the maintenance of the equipment.

### Theory of Radio Pulses from Cosmic Ray Air Showers

THE recent results of Porter *et al.*<sup>1</sup> on detectable polarized radio pulses emitted from extensive air showers cast some serious doubt on the validity of the mechanism for coherent emission suggested by Kahn and Lerche<sup>2</sup>. This mechanism concluded, on the basis of a simple model, that the separation of positive and negative charges by the Earth's magnetic field should produce an observable polarized (east-west) radio signal of some 60,000 flux units  $\times \mu\text{sec}$  at 45 Mc/s for a shower containing some  $10^6$  electrons and positrons. The primary cosmic ray particle energy was taken to be about  $5 \times 10^{15}$  eV. The purpose of this letter is to point out several effects which are ignored in the treatment of Kahn and Lerche which may play a dominant part in modifying both the intensity and polarization of the coherent signal. These are (i) refractive index variations; (ii) Coulomb scattering; (iii) time variation of the shower front.

We shall consider the following factors in turn. The variation of refractive index with height can be shown<sup>3</sup> to be important only for distant showers observed at great height. In the experiments being performed<sup>3-6</sup> this effect does not arise.

The effect of Coulomb scattering is two-fold. If the particles in the shower front are all of the same energy, then, on the assumption that they start at the centre of the shower front at some large height, they are spread across the front as time proceeds. In a steady state, as many particles are produced per unit time in the front as are lost from the front. The total effect, however, is that we can no longer treat the front as two thin rings of opposite charge moving down through the atmosphere but must add up the electric and magnetic fields produced by a continuum of rings each weighted by the ambient number density of positive and negative charges at a given ring site. Second, when the particles in the front are distributed in energy, the effect of Coulomb collisions is different for particles of different energy. It has been calculated<sup>7</sup> that this effect can reduce the effective dipole of the shower front treated as two rings by a factor of the order of 10-100. This in turn leads to an intensity decrease of  $10^2$ - $10^4$  which may then reduce the linear polarization by a similar factor if other processes, such as charge excess<sup>8</sup>, contribute a significant amount to the

coherent radiation field. This they may do particularly when both spatial structure and distribution of energy of the particles in the shower front are allowed for.

Shower fronts are by no means constant in time. It has been shown<sup>2</sup> that a simple exponential decay of a shower front can be taken into account and that this does not seriously alter the emission of radiation from a shower in most situations; and almost certainly not in the experiments currently being performed. Whether a different growth and decay rate influences the emission characteristics significantly is difficult to say without performing the analysis, but we suspect that this is only a minor correction.

Altogether then we believe that the null results obtained<sup>1,3</sup> for the polarization experiments may possibly be accounted for by Coulomb scattering which is ignored in the Kahn and Lerche treatment. A more general theory than that already existing is clearly needed. This should incorporate several model energy and spatial distributions of particles in order to decide how sensitive is the emission of coherent radiation from showers to energy variations among the particles in the shower and, separately, spatial structure of the shower front.

One further possible explanation of the discrepancy between the Kahn and Lerche theory and observation has already been suggested<sup>1</sup>. This is that if showers contain a higher excess of negative charges than was suggested by Askaryan (> 10 per cent), then the coherent space charge emission may dominate, the general idea being to place these electrons at a lower energy than is normally recorded on a Geiger-Müller counter when shower experiments are being performed. One can still keep such electrons at a speed greater than that of light in air.

I thank Drs J. V. Jelley and G. Silvestro for interesting discussions. This work was supported by the US National Aeronautics and Space Administration.

### Random Close Packing and the Heats of Fusion of Argon at High Pressures

Using a random close packed model of the liquid state and a Lennard-Jones 6 : 12 interatomic potential function, the calculations made on the heats of fusion of the inert gases<sup>1</sup> have been extended to high pressures. Despite the difficulties discussed in ref. 1, an attempt has been made to calculate the molar volume change  $\Delta V$  on melting at pressures up to 6,000 atm.

For a change of state, using the second law

$$\Delta U = -p\Delta V + T\Delta S \quad (1)$$

where  $\Delta U$  is the initial energy change of 1 mole,  $p$  is the external pressure,  $T$  the temperature, and  $\Delta S$  the entropy change. For triple point calculations<sup>1</sup> the term  $p\Delta V$  is

negligible; for pressures an order of magnitude higher, it is not. Using the subscripts  $L$  for the liquid,  $S$  for the solid, equation 1 gives

$$(U_L + pV_L) = (U_S + pV_S) + Q \quad (2)$$

where  $Q$  is the latent heat of melting. Thus using the energy summations for a random close packed liquid as in ref. 1, an enthalpy : molar volume curve can be drawn, from which  $V_L$  can be predicted at any pressure. A similar lattice summation gives the corresponding enthalpy curve for the solid.

Unfortunately, there are very few data on  $\Delta V$  above the triple point available for experimental comparison. Bridgman's work<sup>2</sup> on the melting curve of argon is used: he gives values of  $V_S$  and  $V_L$  for pressures of 1,000, 2,000, 4,000 and 6,000 kg/cm<sup>2</sup>. Though not very extensive, these data provide an adequate quantitative test over a wide pressure range. Bridgman also tabulates the latent heat at each pressure using the Clausius-Clapeyron equation; his values are systematically lower than the generally accepted values<sup>3,4</sup>. This raises further difficulties in making experimental comparisons, which are discussed later.

Table 1. VOLUME CHANGE ON MELTING AT DIFFERENT PRESSURE

Pressure (dyne/cm <sup>2</sup> ) $\times 10^{-4}$	$V_S$ (cm <sup>3</sup> )	Ref.	Latent heat (kJ/mole)	Ref.	Implied $V_L$ (cm <sup>3</sup> )	Experi- mental $V_L$ (cm <sup>3</sup> )	Ref.
0.689	24.62	4	1.176	4	28.03 $\pm$ 0.11	28.14	4
0.980	24.84	2	1.097	2	27.93 $\pm$ 0.12	28.04	2
			1.176	4	28.27 $\pm$ 0.13		
1,961	24.49	2	1.093	2	26.04 $\pm$ 0.08	26.20	2
			1.172	2, 4	26.25 $\pm$ 0.07

			1.165	2, 4	25.06 $\pm$ 0.04		
			1.176	4	25.08 $\pm$ 0.04		

Two approaches to the calculations were made: (1) Using Bridgman's<sup>2</sup>  $V_S$  for the solid, the enthalpy curves are used to predict the corresponding  $V_L$ , assuming various latent heat values. The comparison with experiment is shown in Table 1 and Fig. 1. (2) Using Bridgman's<sup>2</sup>  $V_S$  and  $V_L$  values, the heats of fusion are evaluated from the enthalpy curves. The results are shown in Table 2.

Table 2. HEATS OF FUSION AT DIFFERENT PRESSURES

(1) Using Bridgman's "low" latent heat values<sup>2</sup>, the predicted liquid volume is too low, as expected. Because Bridgman's values vary about only 2 per cent over the whole pressure range, however, it is useful to obtain  $V_L$  values for (a) the generally accepted latent heat value at the triple point<sup>4</sup> unchanged throughout the pressure range, and (b) the latent heat value<sup>4</sup> as in a, varied after Bridgman's observed variation<sup>2</sup>.

As shown in Table 1, both a and b give a good experimental fit, the differences between them being insignificant compared with the expected error. Fig. 1 shows the results in graphical form; the theoretical fit is good, and well within Bridgman's experimental variations as

## THE SOLID STATE

## Crystal Structure of Cerium (III) Exchanged Faujasite

THIS communication reports the initial results of our investigation of the crystal chemistry of the rare earth faujasite system. In this investigation a single crystal of faujasite was placed in contact with concentrated cerium nitrate,  $\text{Ce}(\text{NO}_3)_3$ , at room temperature for 6 months. The exchange data of Ames<sup>1</sup> on the cerium exchange of Linde X and our own data (H. S. Sherry, personal communication) suggest that the cerium exchange in the crystal will be approximately 60 per cent, which corresponds to a unit cell composition,  $(\text{Ce}_2\text{O}_3)_6(\text{CaO})_{7.6}(\text{Na}_2\text{O})_{3.9} \cdot 29.5 \text{ Al}_2\text{O}_3 \cdot 133 \text{ SiO}_2 \cdot 270 \text{ H}_2\text{O}$ .

The crystal was ground to a 0.27-mm diameter sphere. Diffraction data were consistent with the previously assigned space group  $Fd3m$ . Three-dimensional intensity data were collected with an integrating Weissenberg camera using copper  $K\alpha$  radiation and multiple film packs. The intensities were measured with a microdensitometer and corrected for Lorentz polarization effects and absorption. No corrections were made for the anomalous scattering of cerium.

The structure was determined using combined least squares<sup>2</sup>, Fourier and difference Fourier techniques. The framework parameters reported by Baur<sup>3</sup> were the basis of the initial structure factor—Fourier map calculations. Scattering matter was found in four non-framework positions. Fig. 1 shows the relative electron density of these non-framework sites. (Framework oxygen had a relative peak height of 17.) The small peaks at  $x = 0.22, 0.30, 0.35$  and  $0.41$  are spurious and did not appear on difference maps which contained no positive or negative peaks larger than 2 on this relative basis. Based on internuclear distances (see Table 1) we attribute the scattering matter at  $x = y = z = 0.0696, 0.1652$  and  $0.264$  to  $\text{Na}(\text{Ca}), \text{H}_2\text{O}$  and  $\text{H}_2\text{O}$  respectively. This is in agreement with Baur's<sup>3</sup> assignment. The hydrated cerium (III) ion is slightly displaced from the special position of set  $d$ , that is,  $\frac{1}{2}, \frac{1}{2}, \frac{1}{2}$ , etc. Although this displacement is not evident from the electron density map (Fig. 1), difference maps indicate a  $0.38 \text{ \AA}$  deviation from the centre of symmetry. With two partial occupancy cerium atoms at the  $SV$  site, the  $R$  value for the 263 largest  $F$ 's dropped from 0.135 to 0.127. The structural parameters of this study are given in Table 2.

The arrangement of  $\text{Na}(\text{Ca})$  and water in the six-membered rings of the sodalite cage is in good agreement with the results of Baur<sup>3</sup>. A new cation site for the faujasite system was found in this study; hydrated

Fig. 1. Comparison of theoretical points with Bridgman's experimental data<sup>3</sup>. —, Bridgman's smoothed curve<sup>2</sup>; O, Bridgman's experimental points<sup>2</sup>; ◇, calculated using Bridgman's latent heat values<sup>2</sup>;  $\square$ , calculated using Clusius and Wiegand's latent heat value for the triple point<sup>4</sup>; ■, experimental triple point using Clusius and Wiegand's molar volumes and latent heat<sup>4</sup>.

shown by the scatter of his experimental points. Because  $a$  and  $b$  give very similar results, only values for case  $a$  are plotted.

(2) The same pattern as in (1) is evident in the second approach. The predicted latent heat value is considerably greater than Bridgman's values, but fits both the modified and unmodified Clusius/Wiegand values<sup>4</sup> within the expected error except for  $P = 0.980 \times 10^6 \text{ dyne/cm}^2$ . There is, however, a large discrepancy between Bridgman's volume figures at this pressure, and those of Clusius and Wiegand<sup>4</sup> at the triple point ( $0.689 \times 10^6 \text{ dyne/cm}^2$ ); it seems generally accepted that greater reliance can be placed on the later Clusius/Wiegand figures<sup>3</sup>.

Thus assuming a spherically symmetrical Lennard-Jones potential function and a random close packed model of liquid argon at its melting point, the energy balance between the external pressure and the internal potential energy is accounted for. At pressures up to nearly 6,000 atm., the predicted volume changes or the predicted latent heats of fusion agree with experiment within the expected error.

Table 3. NON-FRAMEWORK POSITIONS AND OCCUPANCIES IN FAUJASITE TYPE STRUCTURE

Site	Hydrated faujasite <sup>a,b</sup>	Anhydrous Ca <sup>++</sup> exchanged faujasite <sup>c</sup>	Hydrated Linde X <sup>7</sup>	Hydrated Ce <sup>+++</sup> exchanged faujasite
(SI)	Species Population No. ions/uc	Ca 1.0 16	Na 1.0 16	
(SII)	Species Population No. ions/uc	Ca, Na 0.5 16		Na 0.57 18
(SIII)	Species Population No. ions/uc	H <sub>2</sub> O 1.0 32		H <sub>2</sub> O 0.99 32
(SIV)	Species Population No. ions/uc	H <sub>2</sub> O 0.33 11	Ca 0.5 16	Na 1.0 32
(SV)	Species Population No. ions/uc			Ce 0.38 6

be a result of time averaging rather than the result of time invariant spatial distribution.

The position SV at the centre of the 12MR reported here is the fifth non-framework position determined for faujasite (Fig. 2, computer drawn using ORTEP<sup>4</sup>). The other four are: SI, the centre of the double 6MR; SII, within the sodalite cage just outside the double 6MR; SIII, within the sodalite cage in the 6MR opening into the super cage; SIV, in the super cage on the opposite side of the 6MR of SIII. A summary of the non-framework positions in the faujasite structure is given in Table 3. The data on hydrated Linde X would indicate that either synthetic and natural faujasite are somehow different or that in pure sodium faujasite the sodium cations take different positions. In a re-evaluation of Broussard and Shoemaker's data<sup>7</sup>, however, Baur<sup>3</sup> finds that in hydrated Linde X sites I-IV are all partially occupied with population parameters,  $P$ , between 0.3 and 0.8. This is more in line with results on the other hydrated faujasite forms.

Preliminary data obtained with dehydrated cerium (III) exchanged faujasite and fully exchanged LaX indicate that all rare earth ions move from site SV to SII.

## Tubular Ice Crystals

It has been found that on very rare occasions long, thin ice needles grow into the air from the solid surface of water frozen in an open container<sup>1-4</sup>. In the course of supercooling experiments, Dorsey<sup>5</sup> observed a similar phenomenon in the laboratory. He assumed that growth occurred when, because of the increase in volume during solidification, water was forced through an opening in the ice covering the surface. Dorsey also suggested that a tube formed, through which water flowed and which "grew"

Fig. 1. Diagram of the cell showing growth of tubular ice crystal.

at its tip. Recently, Hayward<sup>6</sup> reported a method for growing such spikes and obtained experimental evidence in support of Dorsey's mechanism.

This communication describes a simple method of growing hollow tubes or needles of controlled size, suitable for physical testing; some of the crystallographic characteristics are also reported. We present evidence in support of Dorsey's mechanism, elaborate on it, and suggest a necessary extension. Finally, we indicate how these results can be used for growing tubular bi- or tri-crystals other than ice.

The apparatus used in these experiments consisted of a cell, a cold trap and a rotary vacuum pump. The cell was cylindrical in shape, with a cold finger protruding from the bottom which contained about 20 cm<sup>3</sup> water (Fig. 1). The trap was placed in a mixture of dry ice and acetone or in liquid air and the system was evacuated to a pressure of 10<sup>-1</sup> mm of mercury. Soon after the cell was immersed in the cold bath (-15° to -35° C) dendrite branches started to grow on the water surface. Before it was completely covered with a crust of ice the water surface became hemispherical in shape. Solidification then continued around the edge of the hemisphere and a short section of the tube was thus formed. The continuous flow of water maintained the droplet at the tip of the tube resulting in steady growth.

Some of the tubes were longer than 100 mm and were slightly tapered toward the tip (Fig. 2a). The average diameter varied between 1 and 3 mm with a wall thickness of about 0.2 mm. It was frequently found that the diameter decreased abruptly once or twice during growth. Both the diameter and the length of the secondary tubes were about one order of magnitude smaller than the same dimensions of the primary tubes (Fig. 2b).

Crystallographic orientation was determined in polarized light and with the etch pit technique developed by Higuchi<sup>7</sup>. The specimens were found to be single, bi-, or tri-crystals of random orientation. In all cases investigated the grain boundaries in the bi- and tri-crystals were parallel to the main axis over the entire length of the specimen. Microscope observations showed that the wall of the tube was clear, but the frozen core occasionally contained small bubbles of air or vapour.

With this technique it was possible to observe the process of growth in great detail. The formation of the ice cover, the flow of water through the tube, and growth at the tip were observed visually. The existence of a high water pressure due to freezing was demonstrated by reversing the process which supplied the water flow. When, during tube formation, the cell was lifted from the bath and the ice crust inside the cold finger wall melted, the consequent volume contraction drained the water from the tube of ice. Incidentally, this technique was used to produce hollow tubes. These observations support Dorsey's theory and provide further insight into the mechanism. In general, the rate of extraction of heat from the reservoir (controlled in the present experiments by the temperature and geometry of the bath) determines the rate of flow of water through the tube. The water transported to the tip of the tube has, however, to be frozen with an appropriate speed which is governed by the evaporation rate (pumping speed and trap temperature). The vapour pressure of the water droplet is greater than that of the ice because of its higher temperature and convex surface. Cooling by evaporation is thus concentrated on the water droplet and this method of heat extraction is preferable.

In steady state the amount of water transported from the reservoir in unit time is

$$V = r_i^2 \pi l + (r_o^2 - r_i^2) \pi l s + 2 \pi r_o^2 a \quad (1)$$

where  $r_i$  and  $r_o$  are the inside and outside radii of the tube, respectively;  $l$  is the tube length grown in unit time;  $s$  is the density of ice; and  $a$  is the amount of water evaporated from unit area in unit time. The condition of steady growth, not considering radiation and conduction, is that

$$2 \pi r_o^2 a L_e = (r_o^2 - r_i^2) \pi l s L_f \quad (2)$$

where  $L_e$  and  $L_f$  are the specific heats of evaporation and

Fig. 2. a, Typical ice needle. b, Typical primary and secondary needle formation viewed in polarized light.

freezing, respectively. From equations 1 and 2 the following expression is obtained

$$\frac{V}{\pi} = r_i^2 l + 2r_o^2 a \left( \frac{L_e}{L_f} + l \right) \quad (3)$$

The relatively wide range of conditions under which growth can take place shows that the hemispherical drop at the tip of the tube can accommodate significant changes in  $V$  and in  $a$ . Thus when  $V$  becomes greater than that corresponding to the established equilibrium, the surplus amount of water increases the droplet size and growth continues with increasing  $r_o$  until the steady growth condition described by equations 1 and 2 is again satisfied.

The predictions of equations 1 and 2 were substantiated by experiments, but it is realized that in practice the process is made feasible only by the high surface tension of water and the apparently low polarity of the ice surface<sup>8</sup> which prevents overflow. It follows from our observations that a mechanism composed of water flow and heat flow alone is not sufficient to explain the process and that the introduction of a third component, the surface tension, is necessary. The realization of the essential features of the mechanism leads to the conclusion that tubes from substances other than water could be grown if an experimental technique could be devised to create a suitable mass flow and heat extraction and a balance between them. Indeed, tubes of benzene were grown with a mechanically controlled liquid flow at atmospheric pressure and  $-10^\circ\text{C}$ . In this instance, mass flow was created by artificially forcing benzene through the orifice of a syringe. The surface tension of benzene was high enough to maintain a droplet at the tip when growth was directed downward. The successful growth of benzene tubes is considered good evidence in support of the suggested mechanism. This mechanism thus explains all the previously reported tube formations under various conditions (open air<sup>1-3</sup>, vacuum<sup>5,6</sup>, undercooled<sup>6</sup>) and all the present observations. The recognition of the essential mechanism, furthermore, makes it possible to use this technique to grow tubes of a wide variety of materials.

## CHEMISTRY

### Monomer Solvation of Ion Pairs in Anionic Polymerization

We wish to report some results obtained in a study of the anionic polymerization of styrene in benzene initiated by "living" poly- $\alpha$ -methylstyryl rubidium. Previous workers<sup>1</sup> have shown that at monomer concentrations of  $2 \times 10^{-2}$  mole l.<sup>-1</sup> and below the rate is first order with respect to both "living ends" and monomer, the rate constant for propagation ( $k_p$ ) being  $19.3 \text{ l. mole}^{-1} \text{ sec}^{-1}$  at  $19.5^\circ\text{C}$ .

We have studied the rate of disappearance of styrene dilatometrically in the concentration range  $3 \times 10^{-3}$ – $1 \times 10^{-2}$  mole l.<sup>-1</sup> for the same system at the same temperature and find somewhat more complex behaviour (see Fig. 1). In the region where we can most accurately measure the monomer concentration (above  $2 \times 10^{-2}$

Fig. 1. A plot of  $\log_{10}$  [monomer] against time for run 71 at  $19.5^\circ\text{C}$ . The dotted line represents the predicted  $\log_{10}$  [monomer]-time line calculated from  $k_p = 19.3 \text{ l. mole}^{-1} \text{ sec}^{-1}$  and  $a_0 = 1.17 \times 10^{-4} \text{ mole l.}^{-1}$ .

mole l.<sup>-1</sup>, the reaction is always faster than the results of Roovers and Bywater would predict and is no longer first order with respect to the monomer. Below  $2 \times 10^{-2}$  mole l.<sup>-1</sup> monomer, it seems likely that the results are as predicted though we cannot be sure because the dilatometric data become increasingly unreliable in this range. After an examination of the possible experimental factors which can give rise to this discrepancy (for example, the purification of the materials and the dilatometry itself) we are forced to conclude that the data are correct and thus that a more complex mechanism is operating at monomer concentrations above  $2 \times 10^{-2}$  mole l.<sup>-1</sup>.

We suppose that at monomer concentrations above about  $10^{-2}$  mole l.<sup>-1</sup>, monomer solvated ion pairs are produced (in equilibrium with unsolvated ion pairs) and that they are active in the polymerization. The same mechanism has been proposed<sup>2</sup> to explain results obtained in the anionic polymerization of styrene in tetrahydrofuran at high monomer concentrations.

The mechanism proposed is

$K_2$  is the monomer solvation equilibrium constant.

Such a mechanism gives rise to the rate expression

$$\frac{-d[M]}{dt} = \frac{k_p a_0 [M] \left( 1 + \frac{k_p' K_2}{k_p} [M] \right)}{1 + K_2 [M]}$$

where  $a_0$  is the total concentration of ion pairs present. This equation can be integrated, but the resulting expression is difficult to test. We can rearrange the above equation, however, to the form

$$\frac{R_p}{[M]} = k_p' a_0 - \frac{(R_p - k_p a_0 [M])}{K_2 [M]^2}$$

where

$$R_p = -\frac{d[M]}{dt}$$

Measuring  $R_p$  from the contraction observed over a short time interval and using the value of  $k_p$  quoted earlier, it becomes possible to test the above expression (see Fig. 2).

Fig. 2. A plot of  $R_p/[M]$  against  $\frac{R_p - k_p a_0 [M]}{[M]^2}$  for run 71 at 19.5° C.

Considering the errors involved, the result is satisfactory; Table 1 gives values of  $k'_p$  and  $K_2$  obtained from four runs at 19.5° C treated in the same way.

Table 1.

Run No.	$10^4 a_0$ (mole l. <sup>-1</sup> )	$k'_p$ (l. mole <sup>-1</sup> sec <sup>-1</sup> )	$K_2$ (l. mole <sup>-1</sup> )
69	0.56	36.8	15.8
71	1.17	33.7	13.6
76	2.74	37.1	6.1
77	2.02	39.3	15.2

Clearly the suggested mechanism seems to fit the data well, though more work is required to fix more definitely the values of  $k'_p$  and  $K_2$ . The value of  $k'_p$  indicates that the monomer solvated ion pair is about twice as reactive towards monomer as the ion pair which exists in the absence of monomer. The value of  $K_2$ , though less certain, does indicate that monomer solvated ion pairs should not be present to any great extent below 10<sup>-2</sup> molar styrene, in agreement with the data of Roovers and Bywater.

Because we also have data which indicate the presence of monomer solvated ion pairs when potassium is the counter-ion, and Schulz<sup>2</sup> has postulated their occurrence in tetrahydrofuran when sodium is the counter-ion, it is possible that this is a general phenomenon in all solvents and with all counter-ions. If this is so, it may well be significant in the comparison of results obtained from different systems, carried out in an attempt to understand the effect of solvent and counter-ion on the rate constant, the tacticity of the polymer produced, the interpretation of copolymerization data and the polymerization of monomers other than styrene.

### Hydrocarbon Autoxidation followed by using the Oxygen-Hydrocarbon Charge-transfer Spectrum

It is well known that a solution of oxygen in an organic solvent produces a charge-transfer (CT) spectrum<sup>1-6</sup>, the intensity of which has in some cases been shown to be proportional to the oxygen concentration<sup>2,4,6</sup>. This spectrum is evidently "collisional" in origin, no stable complex being formed between oxygen and the organic compound<sup>2,4</sup>. We have followed the oxygen consumption in a hydrocarbon autoxidation by following the decay of

the CT spectrum. The technique is less sensitive than the traditional measurement of oxygen absorption from the gas phase into a vigorously stirred or shaken solution<sup>7,8</sup>, but it has the advantage of being a simpler technique, measuring oxygen consumption in the solution directly and requiring small amounts of materials.

Hydrocarbon at room temperature was saturated with oxygen in an optical cell which was then sealed with a perforated stopper and placed in the electrically heated cell holder of a 'Unicam SP 800 B' recording spectrophotometer. The stopper prevented oxygen from diffusing into or out of the solution, but allowed thermal expansion. The reaction temperature was reached in about 2 min. The decay of the oxygen-hydrocarbon CT spectrum with time was measured against air at a suitable wavelength. Typical results are shown in Fig. 1. Curve 1 shows the stability of the CT spectrum when oxygen is not being consumed. Curve 2 illustrates the steady depletion of oxygen in an autoxidation with constant initiation rate. Curve 3 shows how the autoxidation accelerates as a low initial concentration of retarder is consumed, attaining finally the same unretarded rate as in curve 2.

Fig. 1. Decay of oxygen-cumene CT spectrum at 60° C (measured against air at 293 mμ). Curve 1, cumene + oxygen; curve 2, cumene + oxygen + 10<sup>-3</sup> molar azo-di-isobutyronitrile; curve 3: cumene + oxygen + 10<sup>-2</sup> molar azo-di-isobutyronitrile + 10<sup>-4</sup> molar 2,6-di-*t*-butyl-4-methylphenol;  $A_0$  and  $A_F$  are initial and final absorbances.

The spectrophotometric data were converted into rates of oxygen consumption using equation (1), in which  $A_0$  and  $A_F$  are the initial and final absorbances of the solution and  $[O_2]_0$  the initial oxygen concentration. In some experiments

$$\frac{d[O_2]}{dt} = \frac{dA}{dt} \times \frac{[O_2]_0}{A_0 - A_F} \quad (1)$$

when the absorbance had fallen to  $A_F$ , the solutions were flushed with white spot nitrogen. No further change in absorbance occurred, thus confirming that all the dissolved oxygen had been used up.  $[O_2]_0$  was calculated from the solubility of oxygen in the hydrocarbon at room temperature, allowing for expansion of the hydrocarbon on heating. This solubility was measured using an adaptation of the method of Bateman, Bolland and Gee<sup>9</sup> in which oxygen was pumped from a known volume of saturated hydrocarbon and measured in a gas burette. The solubility was found to be  $8.5 \times 10^{-3}$  and  $8.6 \times 10^{-3}$  mole/l. in cumene and *p*-cymene respectively at an oxygen pressure of 760 torr.

So far we have made a preliminary kinetic study of the autoxidations of cumene and *p*-cymene, followed at 293 and 305 mμ respectively, in the temperature range 56° to 74° C using azo-di-isobutyronitrile (AZDN) as thermal initiator. In the assumed mechanism<sup>10</sup> shown here,  $X$  is a radical from the initiator,  $f$  the initiator efficiency and  $RH$  the hydrocarbon.

Given stationary state kinetics, long kinetic chains and  $k_2[R\cdot][O_2] \gg k_3[RO_2\cdot][RH]$  it can be shown that

$$\frac{-d[O_2]}{dt} = R = \frac{k_3}{k_{-1}} [RH] R_{\text{eff}} \quad (2)$$

where  $R_i$  is the initiation rate ( $= 2fk_d[\text{AZDN}]$ ). In order to evaluate  $k_3/k_4$ ,<sup>1</sup> it was necessary to measure  $R_i$ . This was done by adding sufficient retarder (2,6-di-*t*-butyl-4-methylphenol, DBMP) to react with the  $\text{RO}_2\cdot$  radicals, making the termination reaction<sup>11,12</sup>

Measurements of the autoxidation rate during the retardation period were treated according to equation 3, in which  $t$  is time and  $[\text{DBMP}]_0$  the initial concentration of retarder

$$\frac{1}{(R-R_i)} = \frac{2k_5}{k_i} \cdot \frac{[\text{DBMP}]_0}{[\text{RH}]} \cdot \frac{1}{R_i} - \frac{k_5}{k_2} \cdot \frac{1}{[\text{RH}]} t \quad (3)$$

From the slope and intercept (on the  $t$  axis) of a linear plot of  $1/(R - R_i)$  against  $t$ ,  $k_5/k_3$ , and  $R_i$  were determined. The accuracy of  $k_5/k_3$  was limited by uncertainties in measuring low initial autoxidation rates.

In Table 1 our preliminary results are compared with earlier work from these laboratories; activation energies ( $E$ ) were derived from Arrhenius plots. Considering the differences in technique, agreement seems satisfactory. Howard and Robb<sup>13</sup> used a thermocouple to determine the heat liberated in an autoxidation; Melville and Richards<sup>8</sup> relied on oxygen absorption measurements.

Table 1. AUTOXIDATION OF CUMENE AND *p*-CYMENE AT 56° C

$k_3/k_4$ (l. <sup>3</sup> /mole <sup>2</sup> /sec.) <sup>†</sup>	$E_3 - \frac{1}{2}E_4$ (kcal/mole)	$k_4/k_3$ Cumene $c. 1 \times 10^4$ $6 \times 10^4$ *	$E_1 - E_2$ (kcal/mole)	Ref.

## Trifluoromethyl-benzimidazoles—a New Family of Acaricides

In a previous communication, the herbicidal activity of certain 2-trifluoromethyl-benzimidazoles having a free hydrogen in the 1 position was described<sup>1</sup>. Although these compounds also possessed promising insecticidal and acaricidal properties their practical use was precluded because of their phytotoxic properties. Further chemical studies made by Newbold and his group<sup>2</sup> have shown, however, that it is possible to retain, and occasionally enhance, the insecticidal activity of the parent benzimidazoles while simultaneously reducing their undesirable herbicidal and mammalian toxicity properties by suitable *N*-substitution. This communication describes the preliminary results obtained with one of these derivatives which has shown promising acaricidal properties—namely, 5,6-dichloro-1-phenoxy-carbonyl-2-trifluoromethyl benzimidazole, to which the code number NC 5016 has been allocated.

Pure NC 5016 is a colourless crystalline solid, melting at 103° C, with a vapour pressure of  $4 \times 10^{-5}$  mm of mercury and a solubility in water at 25° C of 13 p.p.m. Its solubilities in organic solvents are: benzene, more than 40 per cent; dioxane, more than 50 per cent; acetone, more than 50 per cent; ethanol, 2 per cent; and hexane, 1.5-2.0 per cent. The compound is highly lipophilic in nature, and its partition ratio between *cyclohexane* and water is 320 : 1.

The acute oral toxicity values in mg/kg obtained by Sanderson *et al.* are as follows: mouse, 1,600; rat, 240 (female), 280 (male); hamster, 260; guinea-pig, 60; chicken, 50; rabbit, sheep, pig and calf, about 30; dog and cat, more than 50. The acute dermal toxicity to the rat of the 25 per cent W.P. formulation was much greater than 1,000 mg/kg when a 24 h contact period was used. Thus the compound may be considered to have a moderately acute oral and a low dermal toxicity. Long term dietary feeding trials still in progress with rats show a no effect level of about 250 p.p.m. at the 6 month stage.

In the initial insecticide and acaricide tests NC 5016 was found to be active against eggs and adults of the greenhouse red spider, *Tetranychus telarius*, and larvae of cabbage white butterfly, *Pieris brassicae*, as shown in Table 1.

The compound was found to be inactive at normal test rates against the bean aphid, *Megoura viciae*; confused flour beetle, *Tribolium confusum*; brown ear tick, *Rhipicephalus appendiculatus*; housefly, *Musca domestica*:

Table 1

Species	NC 5016	LD <sub>50</sub> level	Standard
<i>Tetranychus telarius</i> adults	36 p.p.m.		10 p.p.m.*
<i>Tetranychus telarius</i> eggs	34 p.p.m.		60 p.p.m.*
<i>Pieris brassicae</i> second instar larvae	$7.8 \times 10^{-3}$ g/cm <sup>2</sup>		$4.5 \times 10^{-2}$ g/cm <sup>2</sup> †

\* Dimethoate standard.  
† Diazinon standard.

yellow fever mosquito, *Aedes aegypti*; German cockroach, *Blattella germanica*; and mealworm, *Tenebrio molitor*.

Further laboratory tests indicated that a single application of 0.03 per cent active ingredient to foliage of the French bean, *Phaseolus vulgaris*, would give effective control of adult *T. telarius* and their eggs for more than 24 days. The compound was also active against dimethoate, phenkapton and chlorobenzilate resistant strains of *T. urticae*. In both soil and foliar application tests no significant systemic insecticidal activity was recorded.

Field trials since 1965 in Britain, South and East Africa, India and Australia (Q. A. Geering, unpublished work) have confirmed the promising acaricidal activity established in these laboratory trials. In particular it is worth noting that good control on apples has been obtained of phosphate resistant *Panonychus ulmi*; and of phosphate-, dicofol- and tetradifon-resistant *Tetranychus urticae* and *T. cinnabarinus*. On citrus *Aceria sheldoni* and *Panonychus citri* have been controlled as well as *Oligonychus coffeae*, *Hemitarsonemus latus* and *Brevipalpus* spp. on tea.

Laboratory tests with worker bees have shown that the compound is inactive at normal application rates as a contact insecticide on glass and as a stomach poison in honey.

No results are available at present on the activity of the compound against other beneficial species, although the spectrum of insecticidal activity is sufficiently narrow to suggest that the hazard to such species would be low. This aspect and the potential development of resistance by mites are currently under investigation.

Fungicidal tests have shown that NC 5016 lacks the activity against mildews often associated with other acaricides.

## IMMUNOLOGY

### Structural Differences within the Gamma G Class of Immunoglobulins

A METHOD of distinguishing two populations of human IgG has been reported<sup>1</sup> recently; it is based on their differing susceptibility towards proteolysis with papain in the absence of cysteine. A papain resistant form is separated intact from the cleavage products of the papain sensitive form by gel filtration on 'Sephadex G-150'. Further evidence for the existence of these two conformational forms of human IgG has since been obtained and it has been established (using conditions of varying concentrations of ethylenediamine tetra-acetic acid) that their differing behaviour on digestion with papain is not caused, for example, by the inactivation of the enzyme by traces of heavy metal ions bound to the resistant form.

We have now investigated the IgG of species such as the rabbit and horse, and this communication describes preliminary results obtained from an investigation of IgG isolated from a group of rabbits. This work was

undertaken to determine whether the conformational characteristics, responsible for differing susceptibility to papain, were influenced by differences in the allotypic determinants located on the heavy chains of rabbit IgG. It seemed to be significant that such determinants have been identified within the Fd part of the heavy chain<sup>2</sup>, close to the site of papain cleavage of the Fc fragment.

The IgG was isolated from the rabbit sera by the DEAE cellulose batch technique<sup>3</sup>, using 0.01 molar phosphate (pH 7.5) as eluent. It was first demonstrated, with preparations isolated from pooled rabbit sera, that rabbit IgG resembled human IgG in that it comprised both papain resistant and papain sensitive forms. Thus by comparing the amount of rabbit IgG recovered undigested (from 'Sephadex G-150' filtration of papain digests performed in the absence of cysteine) with the total quantity of protein treated, the preparation from pooled sera was found to comprise 45 per cent of papain resistant molecules. In the presence of cysteine, however, the total IgG was degraded rapidly and completely to fragments. As in previous work<sup>1</sup> on human IgG therefore it appears that reduction of intra (or inter) chain disulphide bond(s) is essential for cleavage of the papain resistant form.

The results obtained by determining the relative proportions of the papain sensitive and papain resistant forms in a series of rabbit IgG of known allotype are shown in Table 1 (which also includes the results of investigations of the pooled rabbit IgG already mentioned, pooled human IgG and IgG isolated from a rabbit antiserum raised against human leucocytes).

Although all possible rabbit IgG allotypes were not examined, no clear-cut correlation between papain sensitivity and allotype is apparent from this data. Table 1 shows that varying proportions of the papain resistant form, ranging from 66 per cent to almost 100 per cent, were found in the IgG preparations isolated from the sera of the individual rabbits, which were all in the "resting state". It is interesting to note, however, that whereas 85 per cent to 95 per cent of the IgG isolated from "resting" rabbits (7,558 and 7,606) of allotype 3/4 proved to be papain resistant, only 35 per cent of this form was found in the IgG isolated from an immunized rabbit (510) of the same allotype. This animal was one of a series which had been immunized (by six weekly intravenous injections and a recent booster injection) with a suspension of human leucocytes, in an investigation of the effect of anti-leucocyte sera on DNA synthesis by peripheral lymphocytes<sup>4</sup>.

Table 1

IgG sample	Allotype	Percentage papain resistant
Rabbit 5698	1/6	70
7534	1/5	90
7558	3/4	85
532		90
7726	1, 2/4, 5	80
7654	1, 3/4, 5	74
5934	2/4, 6	70
7629	2/4	66
7606	3/4	95
510 (anti-human leucocyte serum)	3/4	35
Pooled rabbit IgG		45
Individual human IgG (type "O" serum)		45

It is significant that, although immunoelectrophoresis of the rabbit anti-leucocyte serum (Fig. 1a) revealed the usual extended IgG precipitin arc (on diffusion against goat anti-rabbit serum), the yield of IgG isolated by the batch DEAE cellulose procedure<sup>3</sup> was unusually small (only 35 per cent). Furthermore, the isolated rabbit IgG showed a restricted IgG precipitin arc of slow mobility (Fig. 1b). The finding therefore that this preparation was comprised predominantly (65 per cent) of papain sensitive molecules agreed with other evidence that electrophoretically slow (human myeloma) IgG molecules are sensitive to papain<sup>5,6</sup>, and that the proportion of

Fig. 1. Immunoelectrophoretic patterns of (a) rabbit 510 serum, (b) rabbit 510 IgG, (c) 0.5 molar sodium chloride eluate of the DEAE cellulose used to prepare (b). (Antiserum: goat anti-rabbit serum.)

papain sensitive molecules found in preparations of IgG depends on their mode of isolation. Because DEAE cellulose, under the conditions of elution which were used (that is, 0.01 molar phosphate, pH 7.5), binds molecules which are negatively charged, the IgG isolated from the rabbit anti-leucocyte antiserum (510) can be assumed to be that portion which is relatively uncharged (that is, the least negative, electrophoretically "slow", molecules). The electrophoretically faster IgG, on the other hand, would be expected to bind to the exchanger in such conditions. This was indicated by immunoelectrophoretic analysis of the IgG fraction of the rabbit anti-lymphocyte serum recovered from the DEAE cellulose by subsequent elution with 0.01 molar phosphate buffer (pH 7.5) containing 0.5 molar sodium chloride. As will be seen from Fig. 1c, the IgG thus eluted gave a relatively fast precipitin arc (on reaction with goat anti-rabbit serum).

It seems likely therefore that the serum of rabbit 510 contained a large concentration of relatively "fast" circulating antibodies, which bind to the DEAE cellulose in 0.01 molar phosphate at pH 7.5. The finding of Sela and Mozes<sup>7</sup> that a positively charged antigen elicits the production of negatively charged antibody molecules and vice versa suggests that the antigenic determinants of the human leucocytes used for immunization possess a net positive charge. This possibility is being examined further in investigations on preparations of IgG isolated from serial samples of rabbit sera, before and after immunization with leucocytes and various well defined antigens.

In the present studies on rabbit IgG, a 4 h incubation period was used in all cases, and digestion to fragments was almost complete when the incubation was carried out in the presence of cysteine. Goodman<sup>8</sup> reported, however, that rabbit IgG is heterogeneous with respect to its cleavage by papain, even in the presence of cysteine and that the most resistant molecules have a large content of carbohydrate. Other workers<sup>9</sup> have shown that human IgG is also heterogeneous with respect to carbohydrate content; the greater the content the faster its electrophoretic mobility. Thus in the light of our findings, it is possible that the relatively papain resistant molecules observed by Goodman originated from the fast mobility fraction. It is of further interest that Fleischman<sup>9</sup> and Utsumi and Karush<sup>10</sup> have concluded, from structural investigations, that there are two points of attachment of carbohydrate to the heavy chain of rabbit IgG. One moiety is recovered in the Fc fragment on papain cleavage, while the second, which is released as a glycopeptide, is located on the heavy chain in the area at which cleavage occurs. If the carbohydrate heterogeneity of the IgG molecules is expressed by the moiety attached to the latter region, then it is possible that molecules with a large content of carbohydrate possess electrostatic (and/or stereochemical) properties which exclude their cleavage by papain without previous unfolding, for example, by the reducing action of cysteine, as suggested here and in our previous work<sup>1</sup>.

In summary, no obvious relationships were observed between rabbit IgG of various allotypes and their susceptibility to papain proteolysis. Immunization seemed to influence the proportion of papain resistant to papain sensitive forms, producing further evidence that papain sensitivity is a function of the surface charge (as reflected by electrophoretic mobility and DEAE cellulose chromatography) of the IgG molecule.

Our other findings (to be reported in detail elsewhere) suggest, however, that a similar effect is not elicited by the immunization of some mammalian species such as the horse.

Dr A. Kelus kindly supplied rabbit sera of known allotype.

### Relative Efficiency of Immune Cytolysis by IgG and IgM Antibodies

BECAUSE Humphrey and Dourmashkin<sup>1</sup> have shown IgM antibody to be more efficient than IgG antibody in causing lysis of erythrocytes in the presence of complement, we considered it of importance to investigate the relative efficiency of IgG and IgM antibodies with regard to nucleated cells.

Antibody to rat kidney was produced in rabbits immunized with rat kidney homogenate emulsified with complete Freund's adjuvant. Monolayers of rat kidney cells were grown on coverslips, the medium consisting of Parker 199 and calf serum (for details of these methods see ref. 2). Globulin was separated from the rabbit serum, which showed complement fixation with rat kidney antigen at a titre of 1:4,096, and gave immune lysis of cultured rat kidney cells in the presence of complement. Globulin components were serially eluted from 'Sephadex G-200', using 0.15 molar phosphate buffer, pH 7.4, in 0.5 molar saline. Material from the two peaks was ultracentrifuged in a sucrose gradient by the method of Kunkel<sup>3</sup>. This demonstrated 19S globulin in the first and 7S in the second 'Sephadex' peak.

The IgG and IgM fractions were diluted to give comparable protein concentrations in the tissue culture medium, after inactivation at 56° for 30 min. Fresh guinea-pig serum was added to a final concentration of 10 per cent to act as a source of complement. Tissue cultures were incubated at 37°. In the presence of 0.74 mg/ml. IgM and complement all cells were destroyed by immune lysis at 24 h after such addition, while only small numbers of cells survived at a concentration of 0.37 mg/ml. On the other hand, a concentration of 0.76 mg IgG/ml. allowed considerable cell survival at 24 h, while at 0.38 mg/ml. there was a good growth of culture cells. As shown in Table 1, complement fixation (50 per cent haemolysis reading) was several times more efficient by IgM than by IgG antibody when considered on a weight

Table 1. COMPARISON OF COMPLEMENT FIXATION (C.F.) OF IgG AND IgM ANTIBODY

'Sephadex' fraction	Protein concentration giving C.F.
IgG	14.1 $\gamma$
IgM	3.6 $\gamma$

basis. Immune cytolysis, if comparison is made on a protein weight basis, thus shows only a marginal difference between IgG and IgM. Because our efforts to produce purified specific anti-kidney cell antibody failed, we were unable to make a comparison on a molecular basis.

Humphrey and Dourmashkin<sup>1</sup>, using isolated antibody against sheep erythrocytes, concluded that two to three molecules of 19S antibody were sufficient to make a hole in the erythrocyte envelope, while of the order of 1,000 times more molecules of 7S antibody were necessary for a similar effect. Greenbury, Moore and Nunn<sup>4</sup>, working with rabbit antibody directed against human A red blood cells, concluded that 19S antibody was more avid, and on a molecular basis 750 times more efficient at agglutinating red cells than 7S antibody. Using anti-Forssman serum and dog kidney culture cells, Sell and Spooner<sup>5</sup> found a relative inefficiency of IgG as opposed to IgM antibody in complement fixation. They found, however, a relative inability of this type of IgM antibody to produce cytolysis of the dog kidney cell; IgM was a much more efficient haemolytic agent than IgG. On a protein weight basis our results also appear to show an insignificantly greater cytolytic power by IgM than by IgG antibody, although this may well indicate that each IgM molecule is a more efficient agent than a corresponding IgG molecule. On the other hand, IgM appeared to be a more efficient complement fixing antibody than IgG.

## BIOCHEMISTRY

### Isolation of Human DNA and its Demonstration by Electron Microscopy

MANY people have purified DNA by a variety of methods and measured its length by electron microscopy<sup>1-4</sup>. The DNA of bacteria and bacteriophage have been used frequently and salmon sperm and mammalian tissues have been used too.

Our experience with isolating human cancer deoxyribonucleo-protein (DNA-P) for use as antigens in immunological experiments has led us to purify further and examine DNA from normal as well as malignant material of human origin<sup>5-11</sup>. The technique which we use for these preparations is a modification of the method of Chargaff<sup>12</sup> and is based on other original work<sup>13-15</sup>. We wanted to demonstrate the DNA isolated from these preparations using electron microscopy so that we could further establish the nature of the antigens used.

All procedures were carried out at 4° C (unless otherwise stated) using aseptic techniques, sterile glassware and instruments, and fresh triple distilled water. The specimen was trimmed of all fat and connective tissue, and weighed and minced for 1 min in a Virtis or Waring homogenizer until it was moderately fine. The homogenized tissue was

washed with two or three volumes of normal saline by centrifugation at 16,000g (10,000 r.p.m.) for 10-20 min in stainless steel cups. This was repeated until the supernatant was visibly clear of fat and red blood cells. Many of the saline soluble proteins and RNA were also removed<sup>12</sup>. All these supernatants were discarded. An equal volume of 1 molar sodium chloride glycine/saline buffer (pH 8.2) was added to the tissue particles. This buffer was prepared by adding 5.85 g of sodium chloride to each 100 ml. of Hyland's glycine/saline buffer. The suspension was put through a Ten Broeck 'Pyrex' homogenizer until it was finely ground and homogeneous. The remaining connective tissue further separated at this stage, for it tended to remain in the grinder as fibrous masses. The resultant suspension was stirred gently, to avoid foaming, with a magnetic stirrer for several hours (usually between 2 and 4) in the cold. To avoid shearing a minimal stirring force was used. This stage was continued until a good gelatinous precipitate was obtained when a small amount of the saline supernatant was added to 95 per cent ethyl alcohol. The remnants of the tissue were removed from the suspension by centrifugation and discarded. The supernatant which contained the DNA-P was precipitated in two volumes of 95 per cent alcohol, pre-cooled to -25° C to counteract the heat produced at this stage<sup>4</sup>. The precipitate appeared in the form of gelatinous strands. The DNA-P was lifted from the solution with a wooden applicator, using a "spooling" action to wind it on the stick. It was washed in 70 per cent and then in 80 per cent ethanol. The DNA-P was redissolved in 200 ml. of 1 molar sodium chloride glycine/saline buffer by stirring overnight in the cold. (For a quantitative yield of DNA a larger quantity of solution is required and a longer time of stirring may be necessary depending on the original mass of tissue.) The solution was centrifuged for 10 min at 4,150g (5,500 r.p.m.) for the separation of the DNA-P from undissolved material. To the solution of DNA-P was added one-third of a volume of a 3:1 chloroform-iso-amyl alcohol mixture. This was stirred for 150 sec and spun for 10 min at 1,465g (3,000 r.p.m.) to effect good separation of the two phases. The saline phase was removed and the previous step was repeated at least three times. The final saline phase was then slowly injected into pre-cooled (-25° C) 95 per cent ethyl alcohol. The DNA fibres that formed were spooled and lifted to drain. The mass was washed by three centrifugations at 1,020g (2,500 r.p.m.) for 7 min using first 70 per cent, then 80 per cent, and finally 100 per cent ethanol. The excess alcohol from the final wash was aspirated from the DNA mass before it was allowed to air dry at 4° C. When dry it was weighed and a 0.1 per cent solution of DNA in 0.15 molar ammonium acetate was prepared. Grids for electron microscopy were prepared by spreading DNA-cytochrome c solutions according to the method of Kleinschmidt and Zahn<sup>3</sup>.

The DNA prepared by this method from a non-cancerous kidney was relatively free from other visible contaminating substances, as can be seen in the electron micrograph (Fig. 1). The average length of the filaments obtained by this method was found to be 1.6  $\mu$  and the weight average length was 3.0  $\mu$ . There are many reasons for this degraded state, not the least of which is the vigorous stirring used when the DNA-P was redissolved in sodium chloride glycine/saline buffer. Cavalieri *et al.*<sup>16</sup> have showed that the vigorous chloroform-amyl alcohol extraction of protein results in fractionation of the larger molecules at the interface so that they are preferentially precipitated with the nucleoproteins. This may account for some of the loss of longer molecules in our preparations, for we made no attempt to prevent this.

For the immunization of rabbits and humans, the antigenic material employed is the human DNA-P extracted by the second centrifugation. Maybe the DNA is already somewhat degraded at this stage, but the length of the fibres obtained on spooling the DNA-P from the solution

Fig. 1. Human kidney DNA, negative print. Weight average molecular length was  $3.0\mu$ . ( $\times 12,500$ .)

suggests that a high degree of degradation had not already occurred. Regardless of possible reduction of molecular size, the DNA-P retained its antigenicity. Further purification of these tissue extracts gives a purified product that resembles the DNA observed from other sources.

We thank Dr Dimitrij Lang of Southwest Centre for Advanced Studies, Dallas, Texas, for the microscopic preparation and for making the length measurements.

This work was supported in part by grants from the US National Institutes of Health.

### Cell Electrophoretic Mobilities in Friend Virus Disease

CHANGES in cell surface charge density have been reported several times in various types of malignancy<sup>1-4</sup>. One of the problems of applying the cell electrophoretic method to such problems is the need to obtain a quantity of single cells in suspension in a medium of known composition. The spleen, however, can be dispersed mechanically with ease, and we have chosen to investigate such spleen cell

suspensions electrophoretically during the course of Friend virus disease, where gross pathological changes occur in the spleen.

Friend virus was injected into young adult *BALB/c* mice. After various intervals, spleens from infected mice and comparable control animals were cut into small pieces and pressed gently through a nylon sieve into 0.145 molar sodium chloride buffered to pH 7.2 with 10 per cent v/v 0.1 molar phosphate buffer. After a few minutes, when debris and cell aggregates had sedimented out, the supernatant cell suspension was taken and washed twice in buffered saline by centrifugation and then resuspended to about  $2.5 \times 10^6$  cells/ml. to give a suspension suitable for electrophoresis. Viability tests were performed using lissamine green<sup>5</sup>, and suspensions containing more than 10 per cent of staining cells were discarded. Electrophoretic measurements were made in a cylindrical cell apparatus of the type described by Bangham *et al.*<sup>6</sup>.

In the saline buffered with phosphate which we used the electrophoretic mobilities of nucleated spleen cell suspensions from control animals showed a bimodal distribution. The two groups of cells had mobilities of  $-0.83 \pm 0.06$  and  $-1.17 \pm 0.08 \mu/\text{sec}/V/\text{cm}$ , respectively (Fig. 1A). In spleen cell suspensions taken from animals infected with Friend virus certain characteristic changes were seen. When the observations were grouped according to spleen weight, mobilities did not differ significantly from normal until the spleens reached about 0.3 g, that is, until about the tenth day of the disease. In larger spleens the ratio of the numbers of faster to slower moving cells increased, until in spleens of more than 0.6 g only fast moving cells were seen. A series of measurements on 187 separate cells from large spleens yielded an average mobility of  $-1.20 \pm 0.11 \mu/\text{sec}/V/\text{cm}$ . In Figs. 1B and 1C are plotted histograms of measurements made on spleens with mean weights 0.43 g and 0.86 g, respectively, which illustrate the aforementioned changes.

Sialic acid residues are important surface charge determinants in a variety of mammalian cell types<sup>7,8</sup>. Accordingly, some experiments were carried out in which spleen cell suspensions from control animals and from animals with advanced disease were incubated with neuraminidase before electrophoresis. Samples (2 ml.) of cell suspension,  $10^7$  cells/ml., were incubated for 30 min at 37° C with 500  $\mu$  of the enzyme. The cells were then washed and resuspended for measurement in buffered saline. Suspensions from normal spleens seemed to be unaffected, showing the same bimodal distribution and characteristic

Fig. 1. (A) Spleen cells of normal mice with mean spleen weight of 0.12 g. (B) Spleen cells from mice infected with Friend virus with mean spleen weight of 0.43 g. (C) Spleen cells from Friend virus-infected mice with mean spleen weight of 0.86 g.

mobilities. In the suspensions of cells from large spleens, however, a proportion of the cells in the population suffered a considerable decrease in electrophoretic mobility. This gave rise once again to a bimodal distribution of mobilities, the two groups of cells having mobilities of  $-0.87 \pm 0.08$  and  $-1.21 \pm 0.09$   $\mu\text{sec/V/cm}$ , respectively.

The most obvious interpretation of these results is that during the course of the splenomegaly associated with Friend virus disease, cells of the normally occurring slow moving group acquire an enhanced surface charge which derives from neuraminidase-labile sialic acid residues. The initial results could equally well be interpreted in terms of a massive overgrowth of the faster moving cell type. The optical limitations of the cylindrical cell type of electrophoresis apparatus do not permit one to make any assessment of cell type on cytological grounds. We cannot therefore at present say what cells are to be found in each electrophoretic group in the normal spleen cell suspension, nor can we seek any confirmation of the foregoing interpretations of the results obtained. It must suffice to say that the cell population from the spleen of an animal with advanced Friend disease lacks an electrophoretically slow moving component present in normal populations of spleen cells, and that by treatment with neuraminidase the population from the diseased spleen can be resolved into two components with mobilities closely similar to those of the two components from normal spleens.

### Ribonuclease Activity in the Ehrlich Ascites Tumour

PREVIOUS studies<sup>1</sup> have revealed a relationship between the distribution of intracellular and extracellular ribonucleases and the phase of growth of *Staphylococcus aureus* strain Duncan. The difficulty of distinguishing between intracellular and extracellular enzymes precludes similar studies on animal tissues, but it was considered desirable to examine such enzymes in the ascites tumour, where separation of cells and ascitic fluid presents no difficulty.

Ellem, Colter and Kuhn<sup>2</sup> have recorded the presence of extracellular and intracellular ribonuclease activity in the Ehrlich ascites tumour. With the strain of Ehrlich ascites tumour used in the present work, the situation

was found to be more complex and the results are recorded because of their relevance to studies of ribonucleases both in ascites tumours and in other animal tissues.

Tumour tissue was kindly supplied by Dr L. G. Lajtha of the Paterson Laboratories, Manchester. In most experiments suspensions of cells were withdrawn approximately eight days after implantation. In some cases, the cell suspensions were contaminated with blood and these were pooled separately. Cells were collected by centrifugation at 3,000*g* for 10 min, and washed twice with normal saline. The washed cells were suspended in 0.1 molar *tris* hydrochloric acid, pH 7.5, and homogenized in a glass homogenizer. Cell debris was removed by centrifugation at 3,000*g* for 30 min and ribonuclease activity was measured at pH 5.5 and pH 7.4, at which values activity was found to be maximal, by a modification of the method of Dickman, Aroskar and Kropf<sup>3</sup>. Enzyme activity was also determined using the ascitic fluid obtained in the first centrifugation. Assays were carried out in the presence of  $10^{-4}$  molar *p*-chloromercuribenzoate ions (PCMB), in presence of 4 molar urea, and without any addition to the incubation mixture.

In all cases, extracts of cells exhibited activity at pH 5.5 both in the presence and absence of PCMB or urea, but were devoid of activity in the alkaline range under all conditions used. In no conditions was activity observed at pH 5.5 in ascitic fluid. Measurement of activity on the alkaline side of neutrality revealed no activity in any conditions in uncontaminated fluid, but fluid contaminated with blood showed activity with an optimum pH of 7.4. This activity was increased by 80 per cent by the addition of PCMB. Contamination by blood was encountered more frequently in the later stages of the growth of the tumours, but no enzyme activity was found in uncontaminated fluid from tumours taken at any stage.

These results suggested that, in the strain of Ehrlich ascites tumour which was used, both the cells and fluid are devoid of alkaline ribonuclease and that the enzyme present in contaminated fluid is derived from the blood. Experiments showed the presence of ribonuclease activity in mouse blood plasma exhibiting maximal activity at pH 7.4. Insufficient blood was available to allow a detailed comparison of this enzyme with that of contaminated ascitic fluid and consequently a comparison was made with the enzyme from mouse pancreas.

Pancreas glands from eighty mice were frozen with solid carbon dioxide and ground in a mortar. All subsequent operations were carried out at 4° C. The powder was stirred for 30 min at 4° C with 100 ml. 0.25 normal sulphuric acid and the suspension centrifuged at 3,000*g*. The clear supernatant was submitted to fractional precipitation with ammonium sulphate. 95 per cent of the enzyme activity of the crude extract was precipitated between 60 and 70 per cent saturation. The solution of this fraction was dialysed against water and freeze-dried. The dried material (4.5 mg) was dissolved in 2 ml. of 0.05 molar *tris* hydrochloric acid (pH 7.5) and chromatographed on a column (1.2 cm × 30 cm) of DEAE cellulose using gradient elution, the initial and final eluting solutions being 0.05 molar *tris* hydrochloric acid (pH 7.5) and 0.2 molar *tris* hydrochloric acid (pH 6.8), respectively. Fractions were analysed for enzyme activity and protein was determined spectroscopically. Six peaks exhibited activity, the principal one containing approximately 49 per cent of the activity of the crude extract and showing a sixty-fold purification. Rechromatography of this fraction on DEAE cellulose gave a single protein-containing peak, possessing all the activity, and examination in the Spinco Model E centrifuge revealed only one component. Electrophoresis in the Tiselius apparatus, however, showed the material to be heterogeneous. The partially purified enzyme showed maximal activity at pH 7.4.

Contaminated cell suspensions from sixty mice were pooled and cooled to 0° C. All subsequent steps were carried out at 4° C. Cells were removed by centrifugation

and the fluid (440 ml.) was saturated with ammonium sulphate. The precipitate was collected by centrifuging and dialysed against water. The resulting solution was submitted to fractionation by the same procedures as described above. 84 per cent of the ribonuclease activity, measured at pH 7.4, was precipitated between 60 and 70 per cent saturation. Chromatography of the partially purified material on DEAE cellulose gave five fractions exhibiting activity. The fraction possessing highest specific activity contained 35 per cent of the activity of the crude protein solution, and was eluted at the same position as the principal enzyme fraction from pancreas. The material from this fraction had been purified forty times. It had maximal activity at pH 7.4 and resembled the pancreatic enzyme in its behaviour on ultracentrifugation and electrophoresis.

We consider that these results are consistent with the hypothesis that the alkaline ribonuclease of contaminated ascitic fluid in tumour-bearing mice is derived via the blood from the host tissues. With the object of obtaining experimental justification for this hypothesis, samples of ascitic fluid were taken from thirty mice, the interval after implantation varying from 4 to 11 days. Samples were individually analysed for ribonuclease activity at pH 7.4 and for iron<sup>4</sup>. The correlation coefficient calculated for these two functions was 0.93. This represents a close correlation and we conclude that the contamination by blood is responsible for the alkaline ribonuclease activity of the fluid of the strain of Ehrlich ascites tumour used.

From the results obtained, it appears that, in the strain of tumour used, both cells and fluid are normally devoid of active alkaline ribonuclease. It also appears probable that the enzyme activity found in the later stages of growth of the tumour is derived from the host tissues. In view of this, it is clear that care must be observed in evaluating the significance of levels of ribonuclease activity in animal tissues.

We thank Dr L. G. Lajtha and Mrs M. V. Haigh for their assistance and the Medical Research Council for financial support.

### Autoradiography of Long-term RNA Metabolism in Rabbit Neurones

ATTEMPTS at studying the metabolism of RNA in neurones by the usual techniques of autoradiography have been hampered because parenteral injections of RNA precursors show very little uptake in the brain, while injections directly into the cerebrospinal fluid produce uneven distribution<sup>1,2</sup>.

We anaesthetized some 3 month old New Zealand white rabbits, weighing 2.5 kg, by intravenous injection of 30 mg of pentobarbital sodium. Puncture of the cisterna magna was then attempted, and if 1.0 c.c. of clear cerebrospinal fluid (CSF) could be removed easily, that CSF was replaced with artificial CSF in which a uridine tracer was dissolved. The tracer used in our experiment was uridine-5-H<sup>3</sup>, which cannot be incorporated into DNA as thymidylic acid unless the tritium label is replaced with a methyl group. Thus as a nucleic acid precursor, it is specific for RNA (ref. 3). No toxic effects were observed in the animals

at the doses used for as long as 50 days after injection of the tracer.

Animals were killed after anaesthesia by intracardiac perfusion with neutral formalin, their heads being packed in crushed ice. The partly fixed brains and spinal cords were then removed and immersed in Bouin fluid for 24 h of fixation. After dehydration in ethanol, representative levels of the cerebral hemispheres, cerebella, medullae oblongatae and cervical, thoracic and lumbar spinal cords were embedded in paraffin and sliced coronally in 4 $\mu$  sections.

The sections were mounted on large (1.5  $\times$  3 in.) glass slides, stained with haematoxylin and eosin, and then processed for autoradiography by the dipping technique<sup>4</sup>, using Kodak 'NTB2' emulsion. Sets of slides were exposed in the dark for 15, 45 and 135 days at 5°C in a dry atmosphere (maintained with 'Drierite' drying agent). Unstained sections were processed identically to make sure that the staining procedure had no effect on the distribution of silver grains.

The process of staining sections before coating them with emulsion evidently can cause desensitization of the latent image in an emulsion (B. M. Kopriwa and J. R. Shea, personal communication). If slides are not developed after a very short exposure time, the grain counts obtained at different intervals will not be a simple, definite function of time. Because of this, grain counts on slides with different exposure times are not comparable at absolute levels. The ratio of the nuclear to cytoplasmic grain counts, however, can be compared because the ratio is a variable that is independent of dosage, emulsion thickness, emulsion sensitivity and the thickness of the tissue section. To test the independence of this ratio from the size of the tracer dose, two animals were injected, one with 2.5  $\mu$ c., the other with 1,000  $\mu$ c. Both animals were killed 4 h later, and the values for the nuclear/cytoplasmic ratio obtained for each animal fell within 1 S.D. of the other.

Animals killed soon after injection were given the tracer in a high concentration in the hope that the labelled fraction of the total uridine incorporated in RNA during that period would be large enough to give significant grain counts. High specific activities were also given to animals to be killed a long time after injection, as it was thought there would be considerable degradation of uridine, with a parallel loss of labelled uridine (Table 1).

Table 1

Dose ( $\mu$ c.)	Time before death	Nuclear grain count (45 day exposure)
200	15 min	4,200
100	30 min	3,373
50	1 h	4,436
25	2 h	555
2.5	4 h	305
50	16 h	1,241
100	64 h	249
200	256 h	2,868
500	50 days	3,980

We found that, within an individual section, the distribution of the tracer was related to the distance from the site of the injection, the subarachnoid space, and the ventricles. The number of silver grains also varied with the type of cell beneath the emulsion. Relatively uniform distribution of the labelled uridine was found throughout the cells of the grey matter of the animals killed at intervals greater than 1 day after injection (Fig. 1) except in the lumbar cord, where there was very little activity even at 50 days. No activity greater than background was found in samples of liver or muscle taken from animals injected with up to 1,000  $\mu$ c. of tritiated uridine, where background was counted in an equal area of emulsion nearby, under which there was no tissue.

The intracellular distribution of the tracer varied characteristically with time; nuclear activity rose and

Fig. 1. Unstained 4 $\mu$  section of medulla and cerebellum from animal killed 10 days after injection of 200  $\mu$ c. uridine-5- $H^3$ : 171 day exposure.

Fig. 2. Top: maximum nuclear concentration, 0.5 h after injecting 50  $\mu$ c.; 45 day exposure. Bottom: high cytoplasmic activity, 256 h after injection 200  $\mu$ c.; 135 day exposure.

fell rapidly, whereas cytoplasmic activity rose and fell more slowly. Nucleolar activity tended to be greater than the remaining nucleoplasm (Fig. 2). In choosing cells for detailed grain counting, the following criteria were required: the cytoplasmic and nuclear membranes had to be intact, the Nissl substance visible, at least two silver grains be over both nucleus and cytoplasm, and the cell be near the subarachnoid space. The variation in intracellular distribution of the tracer was studied in the neurones of the lamina pyramidalis of the area calcarina<sup>5</sup>, the hypoglossal nucleus, and the anterior horns of the cervical cord, and in the Purkinje cells of the cerebellum. The results from the Purkinje cells are presented below because these cells are the largest and most uniform of those studied, giving the smallest standard deviations. Results on the other cells were closely parallel.

Three exposure times were available for each set of slides. The set counted in each animal was the one in

which the average grain count in the nucleus or cytoplasm, whichever was greater, would be about fifty. This was felt to give enough grains so that the mistaken observation of a single grain would not greatly affect the total, yet few enough that distinguishing individual grains was not too difficult. Thirty cells were counted in each set, and independent observations on numerous cells were compared, with variations rarely greater than 2 per cent. Grains over nucleoli were included as a part of the nuclear count, as it was felt that accurate differentiation was impossible. The nuclear/cytoplasmic ratios obtained for the Purkinje cell are shown in Fig. 3.

The autoradiographs indicate only the location of uridine incorporated into large molecules. RNA precursor pools, soluble RNA and some messenger RNA were washed out of the 4 $\mu$  sections during histological processing (Shea, J. R., personal communication). Although the levels of uridine in the CSF were artificially high for a short period after the injection, this would not have accelerated the rate of RNA synthesis because the concentrations of the companion bases were not similarly altered.

Fig. 3 suggests that most of the labelled uridine was initially incorporated in RNA with a short turnover time and with a large proportion in the nucleus at any given time. The value of the nuclear/cytoplasmic ratio decreased slowly with time, but significant levels of activity were present in both nucleus and cytoplasm as long as 50 days after injection. This indicates that, as the RNA with a short turnover time is degraded, there is re-utilization of the labelled uridine within the brain. As the fraction of labelled uridine equilibrates throughout all the RNA uridine pools, the nuclear/cytoplasmic ratio approaches a constant value.

The conclusion that there is significant re-utilization of uridine in the neurone is supported by the observation that, although the tracer was initially confined to cells near the surface, after 24 h it was distributed throughout the brain. This observation suggests that most of the labelled uridine was initially picked up by cells near the surface and utilized in the synthesis of short-lived RNA. When this RNA was broken down, the uridine was released and gradually went into equilibrium with uridine in cells throughout the brain.

The absolute value of grain counts in the sections did not decrease rapidly with time. This suggests that uridine turnover in the brain, either by endogenous synthesis of uridine or by uptake from the blood, does not occur at a rapid rate. This may explain why the demon-

Fig. 3. Log-log relation between nuclear/cytoplasmic ratio and time.

stration of RNA metabolism by the intravenous injection of precursors is so difficult.

### **In vitro Incorporation of Amino-acids into the Contractile Protein of Human Blood Platelets**

BLOOD platelets contain a considerable concentration of protein of which about 21 per cent can be accounted for by fibrinogen, serum albumin and a glycogen-globulin complex<sup>1</sup>. Most of the protein of the platelet consists of the specific contractile protein, thrombosthenin<sup>2,3</sup>, and other uncharacterized protein<sup>4</sup>. The origin of platelet proteins has not been established, but it is likely that albumin and fibrinogen originate in plasma, although no other plasma proteins have been detected in platelets<sup>5</sup>. Platelets are formed by fragmentation of the megakaryocyte<sup>4-6</sup> and do not contain a nucleus. It is possible that the contractile as well as other proteins are already present in the cytoplasm during the maturation of the megakaryocyte. It is also possible that certain proteins are synthesized by the platelet in which ribosomes have been observed<sup>7</sup>. This communication reports the incorporation of amino-acids labelled with carbon-14 into the contractile protein of human blood platelets.

Blood cells were separated by the method of Stefanini and Dameshek<sup>8</sup>, and contaminating erythrocytes were removed from the platelets by differential lysis in hypotonic saline as previously described<sup>1</sup>. The platelets were washed three times with 0.9 per cent sodium chloride and once with a solution of 3 per cent glucose and 0.9 per cent sodium chloride, which was the medium used for later incubations.

Washed platelets (500 mg wet weight) were suspended in 10 ml. of incubation medium containing 2  $\mu$ c. of a reconstituted mixture of labelled L-amino-acids (100  $\mu$ c./ml.). Cell suspensions were incubated at 37° C with continuous shaking. Samples of the incubation mixture were removed at 15 min intervals, chilled and 5 ml. of cold 0.6 normal perchloric acid was added. The precipitate was washed six times with 2 ml. portions of cold 0.6 normal perchloric acid and extracted at room temperature with 5 ml. of a chloroform-ethanol-ether mixture (1 : 2 : 2 v/v). The residue was heated at 70° C for 20 min with 5 ml. of 0.6 normal perchloric acid and the washed residue was dissolved in 1 ml. of 88 per cent formic acid. Samples (0.1 ml.) of the formic acid solution were pipetted on to glass fibre disks (Whatman, Gf/A, 2.1 cm diameter); the disks were dried at 65° C for 40 min and counted in a liquid scintillation counter (Packard 'Tri-Carb', Model 3000) by the method of Davis and Cocking<sup>9</sup>. Protein was determined on the neutralized formic acid samples by the method of Lowry *et al.*<sup>10</sup>. Fig. 1 shows the time course of appearance of the labelled amino-acids into material which is insoluble in hot perchloric acid.

The data presented in Table 1 show that puromycin inhibited the incorporation of labelled amino-acids into

Table 1. INHIBITION BY PUROMYCIN OF INCORPORATION OF LABELLED AMINO-ACIDS INTO MATERIAL INSOLUBLE IN HOT PERCHLORIC ACID

\* Inhibition is expressed as a percentage of the control.

material insoluble in hot perchloric acid. Platelets (250 mg wet weight cells) were incubated at 37° C for 75 min in 3 ml. of incubation medium containing 0.35  $\mu$ c./ml. of the labelled amino-acid mixture.

To determine whether amino-acids could be incorporated into a specific platelet protein, platelets were incubated for 5 h with the labelled amino-acid mixture and after centrifugation at 3,500g for 15 min the cells were washed with unlabelled incubation medium and then washed and suspended in a Weber-Edsall solution<sup>2</sup>. The contractile protein was isolated, purified and characterized as described before<sup>2,11</sup>. The contractile protein was reprecipitated four times and had a specific activity of 1,100 c.p.m./mg of protein. This is an appreciable specific activity in view of the considerable amount of the contractile protein present in these cells (15–20 per cent of the total protein). Dialysis for 48 h of 10 ml. of a 0.5 per cent solution of the contractile protein against repeated changes of 400 ml. of 0.025 molar imidazole-hydrochloric acid buffer, pH 7.0, containing 0.5 molar potassium chloride, did not decrease the radioactivity of the contractile protein. No radioactivity was removed from the contractile protein by electrophoresis on cellulose acetate strips at pH 8.6 and 4.5.

The purified contractile protein (10 mg) was treated with 5 ml. of cold 0.6 normal perchloric acid and then hydrolysed at 100° C for 15 min with 4 ml. of 6 normal hydrochloric acid. After removal of the hydrochloric acid by repeated evaporation to dryness, the residue was dissolved in 0.1 ml. of a pyridyl acetate buffer, pH 4.4 (150 ml. of acetic acid + 90 ml. of pyridine + 8 g of ethylenediamine tetraacetic acid made up to 12 l.), and subjected to high voltage electrophoresis on Whatman No. 3 paper, at 1,500 V for 80 min, followed by chromatography at a right angle to the direction of electrophoresis with 1-butanol-acetic acid-water (3 : 1 : 1 v/v)<sup>12</sup>. Fifteen fractions were detected with a ninhydrin spray. Each fraction was cut out, placed in low potassium glass bottles and

Fig. 1. Incorporation of labelled amino-acids into materials insoluble in perchloric acid. Platelets were incubated in a solution of 3 per cent glucose and 0.9 per cent sodium chloride at 37° C. Samples were removed at 15 min intervals and treated with 0.6 normal perchloric acid. The radioactivity of the washed and extracted residues was determined.

10 ml. of scintillator added (scintillation grade toluene with 0.4 per cent (w/v) 2,5-diphenyloxazole and 0.01 per cent (w/v) 1,4-bis-2-(5-phenyloxazolyl)-benzene<sup>9</sup>). All the ninhydrin-positive fractions were radioactive. Because of differential quenching by the ninhydrin chromogen, it was not possible to compare quantitatively the radioactivity recovered in the fifteen fractions with that present in the contractile protein.

In an attempt to find out more about the distribution of the labelled amino-acids in the contractile protein, the dinitrophenol contractile protein was prepared by a modification of the method of Sanger<sup>13</sup>. The DNP-protein was hydrolysed for 16 h with 6 normal hydrochloric acid at 110°C in a nitrogen atmosphere in a sealed tube. The dinitrophenol-amino-acid derivative(s) contained less than 8 per cent of the total radioactivity of the dinitrophenol-contractile protein.

We conclude from these experiments that labelled amino-acids were incorporated into the contractile protein molecule. The labelled amino-acids appear to be distributed throughout the entire molecule. We have recently reported the presence of a stable mRNA directing the *de novo* synthesis of contractile protein in platelets<sup>14</sup>. An active cell-free protein synthesizing system has been obtained from platelets. The predominant product of this system has been characterized as contractile protein. Isolation of this protein labelled carbon-14 from pulse labelled cells verifies that this is the predominant protein synthesized in platelets both *in vitro* and *in vivo*.

This work was supported in part by grants from the US Public Health Service and the Chicago Heart Association.

Since this communication was submitted our results have been confirmed by Warshaw *et al.*<sup>15</sup>.

### Interpretation of Subbands of Lactic Dehydrogenase Isozymes

THE lactic dehydrogenase (LDH) isozymes of tissue homogenates have been found in some cases to exhibit a regularly increasing number of subbands progressing from isozymes 1 to 5 (that is, 1 isozyme 1, 2 subbands of isozyme 2, 3 subbands of isozyme 3, etc.<sup>1-4</sup>. Such subbands have frequently been interpreted on the basis of a mutant allele, which results in the synthesis of two types

of the A subunits, of which isozyme 5 is composed (or of B subunits, of which isozyme 1 is composed, if the order of subbands is reversed). The hybridization of B subunits with two slightly different types of A subunits would account for the subband distributions observed<sup>2,3</sup>, and the presence of two allelic genes has been supported by genetic evidence<sup>3,4</sup>.

It has recently been demonstrated, however, that a regularly increasing number of subbands can be artificially produced with various human tissues, which did not originally exhibit any subbands<sup>5</sup>. This was accomplished by immersing the tissues in formaldehyde before they were homogenized. This process has now been studied further by producing subbands with formaldehyde in individual purified isozymes. The results obtained, and a consideration of their possible significance in the interpretation of subband patterns, are presented\* in this communication.

Human tissues were obtained from autopsy. The preparation of tissue homogenates, starch gel electrophoresis, and detection of LDH isozymes were conducted as previously described<sup>6</sup>. Purified isozymes were obtained by preparative starch gel electrophoresis.

Each starch gel section, containing an isolated isozyme, was saturated with water or an aqueous solution of formaldehyde, wrapped in 'Saran Wrap', and stored at 3°C for specified periods of time. The isolated isozymes, so processed, were applied to starch gels used for analytical electrophoresis by squeezing each starch section on a small piece of filter paper, and inserting this paper into the second starch gel.

Fig. 1 illustrates the production of subbands by the reaction of formaldehyde in isozymes 2 and 3. The subbands experimentally produced in this manner have a greater mobility than the original isozyme. The effect is not restricted to any particular tissue source or buffer used for the electrophoresis. (When whole homogenates were analysed with the Poulik buffer, the subbands were not clearly resolved<sup>5</sup>, possibly because of more extensive interactions with the isozymes.) The proportion of the total activity in the most rapidly migrating subband

Fig. 1. Production of subbands by formaldehyde. (a) and (b) are samples of unfractionated testes; (b) but not (a) was treated with formaldehyde<sup>5</sup>. (c)–(g) are different portions of purified isozyme 2, from the kidney. (h)–(l) are portions of purified isozyme 3, from the testes. The volume per cent formaldehyde used for treatment was: (c), 0.0; (d), 0.3; (e), 0.3; (f), 1.0; (g), 2.0; (h), 0.0; (i), 0.25; (j), 0.3; (k), 1.0; and (l), 2.0. The time between formaldehyde treatment and application to the starch gel was 68 h for (d); 6 h for (e), (f), and (g); and 20 h for the others. The electrophoresis of samples (a)–(g) was conducted with a phosphate citrate buffer, pH 7.0, and of samples (h)–(l) with the discontinuous buffer of Poulik, pH 8.6 (ref. 5).

Fig. 2. Densitometer curves of samples (e), (f), and (g) of Fig. 1.

increases with increasing reaction time and with increasing formaldehyde concentration. When the concentration is sufficiently high, all of the activity is in the most forward subband.

The effect of formaldehyde concentration is also shown in Fig. 2. Samples (e), (f) and (g) of Fig. 1 were scanned by reflectance densitometry. These curves demonstrate the progressive shift in enzyme activity to the more rapidly migrating subband, as the formaldehyde concentration increases. They also indicate that the stain intensity (or enzyme activity) is of the same order of magnitude for the various samples. Because approximately the same amount of enzyme had been applied to the starch gel in each case, the production of subbands cannot be attributed to a selective inactivation of the enzyme. The production of subbands was not reversed by dialysis. Attempts to produce subbands with acetaldehyde were not successful.

The production of subbands with a purified isozyme demonstrates that no interaction with other isozymes is necessary. The simplest explanation of the results described would appear to be that formaldehyde reacts with a certain proportion of the A subunits, and that the proportion increases with time of reaction and with the formaldehyde concentration. If the A subunits which have reacted with formaldehyde have an increased charge and are designated as A', the various bands observed could be represented by the formulae BBBB for isozyme 1, BBBA and BBBA' for isozyme 2, BBAA, BBA'A' and BBAA' for isozyme 3, and so on. If the formaldehyde concentration is increased until all the subunits react, the subbands would be eliminated but the mobility of the isozymes would be increased. This appears to have occurred with sample (g) in Figs. 1 and 2. It has been reported by Fischer and Lauffer that the reaction of formaldehyde with some of the amino groups of tobacco mosaic virus is irreversible, and results in an increased electrophoretic mobility<sup>7</sup>. It is possible that the reaction of formaldehyde with LDH is of a similar nature.

Because formaldehyde can produce subbands with a greater mobility than that of the unsplit isozyme and 2-mercaptoethanol can produce subbands with less mobility<sup>1,8</sup>, it is possible that more than one type of modification of A subunits can be artificially produced. The presence of a number of subunit species may therefore be caused by either cellular synthesis, by chemical or structural modifications of portions of the subunits, or by a combination of both. (Some bands may also be caused by "nothing dehydrogenase"<sup>9</sup>, but their presence can readily be determined by the use of control gels, without substrate.)

In some cases, more subbands have been detected than can be accounted for by two types of A subunits, but not in a regular distribution pattern which would be anticipated for three or more A subunit species<sup>8,10</sup>. All of the subbands which would be anticipated for a given number of different subunits may not always be detected because of such factors as interactions<sup>8</sup>, lack of sufficient sensitivity or of sufficient resolution, or partial inactivation. Tissues are commonly stored frozen, which can cause both inactivation<sup>11</sup> and production of subbands<sup>12</sup>.

It is possible that the resistance of an LDH subunit to alterations may be affected by the inheritance of metabolic variations other than the synthesis of LDH. In such a case, the subband pattern could give a false impression of the inheritance of genes which control the synthesis of LDH subunits. Because a given number of subunit types, whether caused by cellular synthesis or by alterations after synthesis, can result in the same subband pattern, it may be concluded that the interpretation from subband patterns of the number of different LDH subunits synthesized should be made with caution.

### Does 3,4-Dihydroxyphenylalanine Play a Part in Favism?

FAVISM is a haemolytic anaemia precipitated in some glucose-6-phosphate dehydrogenase (G-6-PD) deficient individuals by the ingestion of fava beans. Although the mechanism of haemolysis in G-6-PD deficient individuals has not been elucidated, it is generally thought that the destruction of reduced glutathione (GSH) is associated with the events which lead to haemolysis<sup>1-3</sup>. It has been shown that drugs which cause haemolysis in G-6-PD deficient individuals produce a loss of GSH in their erythrocytes *in vitro*, although it is usually necessary to use a higher concentration of the drug *in vitro*<sup>1</sup> than *in vivo*.

Fava beans contain some substances which are moderately strong reducing agents, and which could, according to the mechanism previously proposed, cause a loss of GSH in the erythrocytes<sup>4</sup>. One of these agents,  $\beta$ -(3,4-dihydroxyphenyl)-L-alanine (L-DOPA), has been detected in only a limited number of plants, but is present in relatively high concentration in fava beans, mainly in the free state<sup>5-7</sup>. We now present evidence that DOPA causes a loss of GSH in G-6-PD deficient erythrocytes.

Blood was obtained from normal individuals and from G-6-PD deficient males, Negroes and Caucasians. The red blood cells, washed three times in 0.15 molar sodium chloride, were suspended in 0.055 molar sodium chloride, 0.1 molar glycine-glycine, 0.03 molar phosphate buffer, pH 7.4, containing glucose. The suspensions of erythrocytes were incubated without and with added DOPA. Final concentrations were: glucose 10  $\mu$ M/ml. incubation mixture; haematocrit between 30-35 per cent in different experiments; DOPA 3.0, 1.5 and 0.75  $\mu$ M/ml. incubation mixtures. The mixtures were incubated in a metabolic shaker in the presence of air at 37°C for 3 h. GSH content of the incubation mixtures was determined according to the method of Beutler *et al.*<sup>8</sup>.

The results, shown in Table 1, demonstrate that a significant loss of GSH occurred in G-6-PD deficient erythrocytes when suspensions of these cells were incubated

Table 1. GSH LOSS IN NORMAL AND IN G-6-PD DEFICIENT ERYTHROCYTES INCUBATED IN THE PRESENCE OF DOPA

DOPA ( $\mu$ m/ml. inc. mix.)	GSH loss ( $\mu$ m/ml. inc. mix.)

0.75				0.10	0.17	0.08	0.15	
1.50				0.17	0.23	0.20	0.23	
3.00	0.04	0.00	0.06	0.01	0.33	0.31	0.32	0.36
Maximum possible loss*	0.58	0.69	0.74	0.70	0.75	0.89	0.46	0.52

\* GSH content of control samples ( $\mu$ m/ml. incubation mixture).

in the presence of DOPA. Normal red blood cells were able to maintain their GSH content when incubated under the same conditions. Oxidation of GSH in normal erythrocytes by DOPA could be demonstrated only in the absence of glucose, that is, in the absence of a source which generated reduced nicotinamide-adenine dinucleotide phosphate.

The results reported here indicate that DOPA causes a non-stoichiometric loss of GSH in the G-6-PD deficient cells. Another agent with a similar action is divicine, the aglycone of vicine<sup>9,10</sup>. It is difficult at present to evaluate the participation of divicine and DOPA (Fig. 1) in oxidation of GSH by fava bean or fava bean extracts. Lack of information on possible synergistic effects (according to the multiple step mechanism previously described<sup>4</sup>) makes interpretation of results obtained with single compounds difficult. There are no data available on the fate of the glycosides *in vivo*, nor on the concentrations of the possible active agents in the blood.

Epinephrine causes some diminution of the glutathione content within the human red blood cell<sup>11</sup>. Non-enzymatic oxidation of DOPA and catecholamines, through reaction with oxyhaemoglobin, may play some part in normal physiology. The possibility also arises that DOPA and catecholamines contribute to the destruction of GSH under physiological conditions in G-6-PD deficient individuals, accounting in part for the shortened life span of erythrocytes found in these individuals without exposure to drugs<sup>12</sup>.

Because only some G-6-PD deficient individuals experience acute haemolysis after ingestion of fava beans, genetically determined factors may control the reaction to the active principles in fava beans<sup>13,14</sup>. The variation in the quantity and state of the potential active agents in the beans, as well as the mode of preparation, could account for the fact that individuals, suffering acute haemolysis induced by fava beans, may have eaten the beans many times previously or afterwards without

adverse reaction<sup>12</sup>. Further work is required on the active principles in fava bean and on the possible pathways for their metabolism in order to clarify the interaction between the genetic and environmental factors in favism.

### Surface Potential of a di-Palmitoyl Lecithin Monolayer when Acetylcholine is in the [Sub-phase

Hyono and Kuriyama<sup>1</sup> described an unusual property of a monolayer of purified egg lecithin when potassium or acetylcholine ions are present in the sub-phase. They observed a plateau in the surface pressure-surface area characteristics that occurred at about 2 dynes/cm and at molecular areas greater than about 100 Å<sup>2</sup>. This type of isotherm had not been observed before in the case of potassium ions<sup>2,3</sup> and we did not find it in the case of potassium or acetylcholine ions either. We wish, however, to point out another property of these systems that may be of general interest.

In our experiments we used the same technique for measuring surface pressure, the vertical plate method (using a sand-blasted platinum plate which was easily cleaned in an oxidizing flame), but we used slightly greater concentrations of salt in the sub-phase. Our results for the surface pressure-surface area measurements at 25°C for monolayers of synthetic di-palmitoyl lecithin give an extrapolated value (from the linear region above 30 dynes/cm) for the molecular area at zero compression as 51.0 Å<sup>2</sup>/molecule. This value, as well as the general shape of the curve, agrees with values in the literature<sup>2-4</sup>. We wish to emphasize that the curve for lecithin did not change significantly when K<sup>+</sup>, NH<sub>4</sub><sup>+</sup> (CH<sub>3</sub>)<sub>4</sub>N<sup>+</sup> or acetylcholine were substituted for Na<sup>+</sup>. The observations of Hyono and Kuriyama may have resulted from the use of lecithin from egg yolk or, as they<sup>1</sup> suggest, from the spreading of the monolayer with benzene as the solvent.

Measurements of surface potential can also be used to characterize monolayers, and so we have made these measurements on monolayers of lecithin using a radium-226 air electrode and a Keithley Electrometer as described before<sup>5</sup>. Fig. 1 shows the curves for the variation in surface potential, ΔV, of a monolayer of synthetic di-palmitoyl

Fig. 1.

Fig. 1. The surface potential of a monolayer of lecithin as a function of the surface pressure. (A) The sub-phase contains 0.1 molar sodium chloride, and (B) the sub-phase contains 0.1 molar acetylcholine chloride.

lecithin as a function of surface pressure (curve A). These values agree with the values in the literature<sup>4,5</sup>. When acetylcholine is present in the sub-phase (curve B), the potentials are greater at all surface pressures and differ by about 50 mV at greater surface pressures. The increase in surface potential is most noticeable in the low pressure region. This change in potential was also found when  $\text{NH}_4^+$  or  $(\text{CH}_3)_4\text{N}^+$  were used instead of  $\text{Na}^+$ , but not when potassium ions were substituted. The data for  $\text{NH}_4^+$  tended to be slightly above curve B and those for  $(\text{CH}_3)_4\text{N}^+$  were slightly below. (This observation must be noted in conjunction with the known depolarizing properties of ammonium, tetraethylammonium, or acetylcholine on biological membranes.) The changes in potential occurred with no change in the surface isotherm emphasizing that the packing in the monolayer did not change appreciably at a time when the charge distribution was varying. When acetylcholine is present to a slight extent (0.01 molar) in addition to 0.1 molar  $\text{Na}^+$ , it has the same effect as 0.1 molar acetylcholine used alone. This no doubt results from the surface active nature of acetylcholine and may be a significant property in the physiological role of this substance.

These data indicate that acetylcholine somehow affects the surface properties of monolayers of lecithin but that the change in potential occurs with several agents ( $\text{NH}_4^+$ ,  $(\text{CH}_3)_4\text{N}^+$  and acetylcholine<sup>+</sup>) implying a rather non-specific type of interaction between fairly large positive ions and the amphoteric monolayers. The effects of the larger cations differ from those of  $\text{Na}^+$  and  $\text{K}^+$ , and so specific adsorption effects are considerable and the surface potential change need not be the same for all monovalent cations in the surface.

Although the changes in surface potential have been used in the past (for example, ref. 3) to analyse the orientation of dipoles in the surface, the interpretations in terms of dipoles caused by the spread molecule alone are always somewhat ambiguous, because of the unknown contribution of the water dipoles in the surface. This contribution may be considerable as has been shown in the case of the adsorption of a monolayer of benzene<sup>6</sup>, which is not even dipolar.

The data described in this communication are part of an attempt to determine the mechanical and electrical properties of monolayers of plasma membrane components as affected by the ionic environment and by substances which are known to change membrane permeability and potential. By investigating the effect of membrane depolarizing agents on monolayers of lecithin, it has been shown that depolarizing agents can affect the interfacial charge distribution or potential without altering the packing in the monolayer.

Although surface potentials have been used to investigate surface structure, their relevance to ion transport

processes in biological systems has been minimized largely because this kind of potential cannot account directly for the currents that flow across membranes. Changes in phase boundary potentials may affect the distribution and flow of other charged species, and so they may be involved indirectly in the mechanism of action of many substances on natural membranes.

In conclusion, although our measurements of surface pressure agree with those in the literature and are therefore clearly different from those reported by Hyono and Kuriyama, the measurements of surface potential indicate that acetylcholine (but not potassium) has a considerable effect on the monolayer of lecithin, especially at low surface pressure.

### Increased Lactate Dehydrogenase 3 in Serum after Myocardial Infarction

SINCE the first report of lactate dehydrogenase (LDH) isoenzymes in human serum<sup>1</sup> a variety of different techniques has been employed to demonstrate them in serum and tissues. There is general agreement, however, that heart muscle contains predominantly the fast-moving isoenzymes lactate dehydrogenase 1 and 2 and that these are present in increased quantities in the sera of patients who have suffered a myocardial infarction, remaining demonstrably elevated for 1-3 weeks after the onset of the attack<sup>2</sup>.

While using cellulose acetate gel 'Cellogel' block as a support medium for electrophoresis of isoenzymes<sup>3</sup> we have noticed a prominent band of lactate dehydrogenase 3 in the sera of post-myocardial infarction cases, in addition to the increased bands of LDH1 and LDH2. Chromoscan reflectance scanning estimated this LDH3 to vary from 0 per cent to 30 per cent (Fig. 1) of the total content of isoenzyme. Very little, if any, LDH4 and 5 was detected, probably because samples were examined for the first 5 days only, before the liver damage, which sometimes follows myocardial infarction, had developed, and also because the inoculum was kept at concentrations compatible with accurate scanning. We felt this to be a valid finding, because we had carefully controlled the method and obtained good duplication of results. A similar degree of accuracy has been claimed for 'Strip' cellulose acetate<sup>4</sup>. We had not found these large concentrations of LDH3 when using starch or agar gels, and attributed them to the sensitivity of the 'Cellogel', because the electrophoretic run is short and heating effects at a minimum. It is well known that variations in the support media can affect the isoenzyme pattern<sup>5,6</sup>, as can buffer<sup>7</sup> and heat<sup>8</sup> which tends to inhibit the slower-moving isoenzymes.

It seemed that the increase in LDH3 could be explained in two ways. The increase could be part of a second iso-

Fig. 1. Maximum activity of LDH3 found in the serum of fifty post-myocardial infarction cases. The largest number (fourteen of the fifty cases) had activities of LDH3 varying from 6 per cent to 10 per cent of the total isoenzyme activity; none had more than 30 per cent, and in one case no LDH3 at all was demonstrated.

enzyme pattern superimposed on that of myocardial infarction, which could occur with shock<sup>9,10</sup>. Alternatively, the increase could be caused by liberation from necrosed heart tissue, along with LDH1 and 2.

To investigate this finding and its possible clinical implications, we examined sera from fifty post-myocardial infarction cases, serially for the first 5 days from onset. The diagnosis had been firmly established on clinical grounds and by electrocardiographic evidence in the form of convex *S-T* segment elevation and deep symmetrical *T* wave inversion, followed by the development of *Q-S* complexes or abnormal *Q* waves (that is, of 0.04 sec or more in width). LDH3 seemed to achieve a peak excretion shortly after infarction (Fig. 2) and so we used this maximum as a parameter for comparison against the following clinical data, which included several factors associated with shock: (a) lowest blood pressure recorded; (b) pulse rate; (c) age; (d) sex; (e) site and size of infarct; (f) previous history of angina; and (g) recovery. No correlation at all with any of these features was apparent.

Several sera from cases brought to the casualty department in varying degrees of shock were examined, but a significantly elevated concentration of LDH3 was not

Fig. 2. Serial serum enzyme estimations from one of the fifty cases of myocardial infarction showing the relative distribution of the faster isoenzymes LDH1, 2 and 3. Peak excretion of LDH3 was on the second day, and a further infarction occurred on the seventh day. Black columns, LDH1; stippled columns, LDH2; white columns, LDH3.

found consistently. Changes were very non-specific when principal organs were not damaged and took more than 2 h to become apparent.

"Sludging" or aggregation of red blood cells in the arterioles has been described as a feature of shock<sup>11,12</sup>. The maximum content of LDH3 in the red blood cell appears to be about 15 per cent<sup>13</sup>. Our method of analysis enabled us to confirm this as an average figure, by examination of several normal red cell extracts, but we considered that if a red cell isoenzyme pattern had been present as well as that of myocardial infarction, an alteration in the ratio of LDH1:LDH2 would also occur, because of interference by the LDH1 and 2 of the red cell, which occurs in reverse ratio to those of heart muscle. This had not occurred nor had we ever detected haemoglobin absorption bands in the sera. Considering all these findings we felt the weight of evidence to be against the LDH3 being a product of shock.

We examined autopsy heart muscle from several cases of myocardial infarction. Taking sections across the necrosed, ischaemic, and normal heart tissue in close proximity, we found that the ratio of LDH1:LDH2:LDH3 was very similar for each individual section of tissue, although total activity of the enzyme was greatly reduced in the necrosed area, as would be expected (Table 1).

Table 1. RELATIVE PROPORTIONS OF LDH1, 2 AND 3 IN HEART MUSCLE TAKEN FROM AUTOPSY MATERIAL IN CASES OF MYOCARDIAL INFARCTION

Case	Necrosed tissue LDH (per cent)			Ischaemic tissue LDH (per cent)			Normal tissue LDH (per cent)		
	1	2	3	1	2	3	1	2	3
1	40	38	22	42	40	18	42	40	18
2	40	33	27	39	36	25	39	37	24
3	70	28	2	57	31	12	63	30	7

Table 2. RELATIVE PROPORTIONS OF LDH1, 2 AND 3 IN HEART TISSUE TAKEN FROM NORMAL HEARTS AT AUTOPSY

Case	Ventricle LDH (per cent)			Septum LDH (per cent)			Atrium LDH (per cent)		
	1	2	3	1	2	3	1	2	3
1	64	32	4	66	30	4	61	31	8
2	56	38	6	54	40	6	54	38	8
3	49	42	9	49	42	9	49	38	13
4	46	42	12	45	42	13	36	44	20

Tissue from normal human hearts showed variation in the ratios of LDH1:LDH2:LDH3 according to the site of the sample. Atria seemed to vary considerably (Table 2). The concentrations of LDH3 in the tissues were slightly lower than in the serum, and we attributed this to post-mortem changes and the greater instability of LDH3. We have found, for instance, that when serum from post-myocardial infarction cases stands on the bench overnight the activity of LDH3 decreases to a much greater extent than that of LDH1 and 2.

It is reasonable to suppose, therefore, that some loss of activity of LDH3 also occurs after death and, because of the relative freshness and ease of preservation of serum, the content of LDH3 in serum from post-myocardial infarction cases represents the content of this isoenzyme of heart muscle more accurately than tissue extracts. The greatest content of LDH3 in human heart muscle appears to have been given as 16 per cent<sup>14</sup>. Although there are many shortcomings in our method of analysis, it does have the advantage of permitting large numbers of specimens to be examined with only minimal loss of LDH3.

Our findings therefore indicate that (a) the source of the LDH3 band frequently found in the sera of post-myocardial infarction cases, when 'CelloGel' block is used for isoenzyme electrophoresis, is necrotic myocardium; (b) the content of LDH3 in human heart muscle is probably greater than previously reported; and (c) there is an individual variation in the content of LDH3 in human heart muscle.

Although we were unable to correlate the concentration of LDH3 with any clinical data, it is interesting to note that the only case where none of this isoenzyme was present was that of an Indian seaman who had suffered a myocardial infarction. Unfortunately, this was the only case of a non-European we examined.

We thank Dr S. M. Wong and Mr T. Byrne for their assistance.

## Serum Iron Transport in the Fowl and the Mammal

It is known that in the vertebrates serum iron is transported as a transferrin complex and thus metallic toxicity in the ionic form does not occur. On the other hand, the existence of conalbumin<sup>1</sup> has been demonstrated in the serum of hens. It is a characteristic protein of egg white, the chemical and physical properties<sup>2-5</sup> of which are like those of serum iron. Immunological assay shows them to be identical<sup>5,6</sup>.

During laying periods in birds, the serum iron increases by a factor of almost five<sup>7,8</sup>. We have now observed that the serum iron values are higher than the iron binding capacity obtained by Ramsay's methods<sup>9,10</sup>. We have also observed this in other species<sup>11</sup> and we have suggested that there is an auxiliary mechanism responsible for serum transport in birds.

In the present investigation we have studied *in vitro* eighteen pooled sera from 280 fowls which had been divided into groups with similar characteristics (sex, age, laying period) and twenty-two sera from two species of mammals (lambs and bulls), in order to determine their iron transport capacities. The serum iron and the iron binding capacity were determined according to Ramsay's methods<sup>9,10</sup>.

The *in vitro* studies were carried out by the addition of known amounts of iron to the serum (70, 140, 210, 300, 400 and 500  $\mu$ g iron/100 ml. serum) and by the precipitation of the proteins by a saturated solution of ammonium sulphate. The determination of iron in the filtrate was made by Klein's technique for evaluation of the unsaturated iron binding capacity<sup>12</sup>.

Fig. 1. Regression lines in hens (A), chickens (B) and the theoretical relation (T) between the iron added and the free iron in the serum.

The relation between the iron added (X) and the free iron (Y) in the filtrate was calculated for the chickens ( $Y = 0.426X - 61.0$ ) and for the hens ( $Y = 0.11X - 7.10$ ). The corresponding regression lines are drawn in Fig. 1. The theoretical line (T, Fig. 1) was obtained from the average values in the chickens (Table 1) by subtracting the iron binding capacity from the sum of the serum iron and the added iron. The data from laying and non-laying hens have been grouped together because they are indistinguishable. The similarities between the two sets are fallacious, however, because from Table 1 it can be seen that although the total unsaturated iron binding capacity is almost the same, the total iron binding capacity is higher in laying than in non-laying hens. This results from the clear-cut differences in the non-Ramsay iron binding capacity fraction. In the laying hens the unsaturated iron binding capacity is zero, as has previously been observed<sup>8,11,13</sup>. The unsaturated iron binding capacity of non-laying hens is similar to that of male chickens.

Table 1. SERUM IRON (SI), IRON BINDING CAPACITY (IBC), UNSATURATED IRON BINDING CAPACITY (UIBC) AND DATA ON *in vitro* FIXATION OF IRON IN HENS AND CHICKENS

L, Laying; NL, non-laying.

The hen sera have the greatest capacity for fixing iron *in vitro* and this was clearly demonstrated with radioactive iron (Fig. 2). A dose of iron-59 was added (0.40  $\mu$ Ci/ml. serum) and the radioactivity was measured in samples of dry filtrate with a Philips Geiger-Müller counter. The serum proteins were precipitated with a saturated solution of ammonium sulphate.

In mammal sera the results of iron fixation *in vitro* fit theoretical predictions well (Fig. 3). The values which were obtained in these experiments showed the same unsaturated iron binding capacity in lambs and bulls (165  $\mu$ g iron/100 ml. serum), which has not been the case with

Fig. 2. Variations in the radioactivity in the protein-free serum filtrate after addition of the same amount of iron-59 and increasing concentrations of stable iron. The data are corrected to avoid the varying dilution of the radioactivity.

Fig. 3. Relation between the iron added and the free iron in the serum of mammals (●) against the theoretical values (○) obtained by subtracting the average values of the iron binding capacity from the sum of serum iron and µg iron added per cent.

other specimens<sup>14</sup>, and for this reason we have averaged all data from *in vitro* experiments.

Our studies on the transport of serum iron in birds point to the existence of an auxiliary mechanism in the transferrin system and suggest that the conalbumin mechanism is the more plausible. Marshall and Deutsch<sup>1</sup> have already described the relation of this protein to iron transport.

We have observed<sup>15</sup> increased values of serum conalbumin in hens, especially laying ones. The existence of the conalbumin in the serum may explain the inverted values of serum iron and iron binding capacity obtained by Ramsay's methods. The values for the iron binding capacity relate to the transferrin only, because when Ramsay's method<sup>10</sup> is applied to a conalbumin-iron solution, the magnesium carbonate used in it fixes all the iron from the complex and, in laying birds, determinations of the serum iron in serum previously treated with magnesium carbonate give values very near to those of the iron binding capacity<sup>11</sup>.

In the different species of birds studied<sup>15,16</sup>, we have found a proportionality between conalbumin serum concentration and the variations of the serum iron according to the frequency and intensity of the laying period. It has already been demonstrated<sup>17</sup> that iron metabolism is activated for egg production in laying birds.

### Lipid Material in the Bone Marrow of a Patient with an Idiopathic Refractory Anaemia

RECENTLY, we found that bone marrow aspirated from a Nigerian boy with an unexplained refractory anaemia contained what appeared to be numerous crystals of a lipid material deposited within the fat globules.

The patient was a 10 year old boy from the Jos Plateau of Northern Nigeria. He had been suffering from general ill-health for about 4 years, during which time he had been given a large number of unspecified drugs by his father. A chronic refractory anaemia had been recognized for about 18 months. Both parents and three elder sisters were alive and well. On admission to University College Hospital, Ibadan (August 23, 1965), the boy was found to be well nourished and he showed no outward abnormality other than gross pallor.

The results of haematological investigations at this time were as follows:

Haemoglobin, 3.5 g per 100 ml.; packed cell volume, 11 per cent; mean corpuscular haemoglobin concentration, 32 per cent; reticulocyte index, 0.5; red cells were normochromic, showing great anisocytosis and slight poikilocytosis; white blood cells, 5,000/mm<sup>3</sup>; neutrophils 68 per cent; eosinophils 1 per cent; lymphocytes 29 per cent; monocytes 2 per cent; platelets less than 10,000/mm<sup>3</sup>.

Bone marrow aspirates from both anterior iliac crests and the sternum showed some hypoplastic fragments, but also many areas of erythroid hyperplasia with "megalo-blastoid" change; the white cell precursors appeared normal and the megakaryocytes were scanty. An outstanding feature of the marrow preparation was the crystalline deposit. Stainable intracellular iron was plentiful, but no ringed sideroblasts were seen. The periodic acid-Schiff staining was normal; the osmotic fragility, normal; haemoglobin electrophoresis, AA; serum vitamin B<sub>12</sub> (*Lactobacillus leichmannii*) 2,000 pg/ml. (upper limit of normal for Nigerians). The serum folic acid activity was not estimated because the patient had received folic acid before admission to the hospital. Studies of the survival of the patient's red blood cells by labelling them with chromium-51 showed a survival in the patient of 20.5 days (normal 25-35 days), but with a suggestion of two cell populations, one with a rapid destruction ( $T_{\frac{1}{2}}$  chromium-51 = 3.5 days).

The patient was observed in hospital for more than 2 months. During this time therapeutic trials of folic acid (5 mg/day), vitamin B<sub>12</sub> (500 µg/day intramuscularly

Fig. 1. Unstained smear of marrow tissue from the patient with unexplained refractory anaemia, fixed in methanol, showing numerous crystals within the spaces left by fat globules ( $\times c. 100$ ).

Fig. 2. A single deposit of crystals ( $\times c. 500$ ).

for 1 week) and pyridoxine (150 mg/day for 1 week) were carried out. The packed cell volume remained 9–13 per cent, the reticulocyte index 0.5–1.5, the white blood cells 700–3,400/mm<sup>3</sup>, and the platelets less than 10,000 to 23,000/mm<sup>3</sup>. After 2 months the patient was given a transfusion of fresh blood and sent home.

Bone marrow tissue removed from the boy was aspirated and smears made. As the smears dried a white efflorescence appeared and this became more obvious when the smears were fixed in absolute methanol for 20 min. Microscopically, the preparations showed irregular spherical crystals 15–25 $\mu$  in diameter within the spaces left by fat globules after fixation (Figs. 1 and 2). The material dissolved rapidly in the immersion oil, leaving behind a faint reticulum which stained light blue with May-Grünwald and Giemsa stain. It was also soluble in 70 per cent ethanol, acetone and a mixture of chloroform and methanol. It was insoluble in water, absolute alcohol and 0.1 normal hydrochloric acid. It was not stained by May-Grünwald and Giemsa, periodic acid-Schiff, ninhydrin or toluidine blue, but did take up sudan black and sudan III and IV.

On tissue culture the crystals grew out of the fat globules within 24 h. Similar crystals have been observed frequently, but only after many days of culture, and have been dismissed as unimportant artefacts of dying cultures.

Since the original observation, similar crystals showing these properties have been seen in many patients, including five out of thirteen patients with megaloblastic anaemia in pregnancy, four out of nine patients with anaemia secondary to chronic infection, and two out of seven patients with various malignant neoplasms. In all these patients the crystals were present in very small numbers.

Extracts of marrow tissue were investigated from the patient and from two patients with Hodgkin's disease and one with chronic nephritis. The three control marrows did not show a crystalline deposit. Marrow tissue which had previously been dried on glass slides was fixed in two changes of methanol for 40 min, and extracted with chloroform-methanol (2:1, v/v) according to the procedure of Folch *et al.*<sup>1</sup>. The lipid extract was washed with one-fifth volume of 0.1 molar potassium chloride and the resulting two phases separated by centrifugation. The upper aqueous phase, containing ganglioside-like substances and other water soluble substances, was siphoned off, dialysed against several volumes of water and evaporated to dryness in a rotary vacuum evaporator. The lower organic phase was washed several times with portions of the pure upper phase of chloroform-methanol-potassium chloride (3:48:47, v/v) (ref. 1). The resulting organic phase was evaporated to dryness.

The residue from the upper-phase fraction was dissolved in chloroform-methanol and subjected to thin-layer chromatography on silica gel G (Merck, A.G., Darmstadt). The chromatogram was developed in a mixture of *n*-propanol-water (7:3, v/v). Substances containing neuraminic acid were detected on the plates by spraying them with resorcinol reagent<sup>2</sup>. The residue from the lower organic phase, containing several lipid spots, was also subjected to thin-layer chromatography on silica gel G. The chromatogram was developed in a mixture of chloroform-methanol-water (65:25:4, v/v). The separate lipid components were detected by spraying the plates with 50 per cent sulphuric acid followed by heating.

Cholesterol esters, cholesterol and phospholipids were demonstrated in the lower phase fractions of all the marrow extracts examined, but no significant accumulations were observed either in the extracts from the patient with refractory anaemia or in the three controls. The upper aqueous fractions showed an accumulation of a material containing neuraminic acid in the patient with refractory anaemia, however, and only trace amounts in the three controls.

The aetiology of the anaemia in this patient remains obscure. There was a pancytopenia, and the marrow showed hypoplastic fragments and other fragments with considerable activity and abnormal normoblasts. These observations and the studies of the survival of red blood cells suggest inefficient erythropoiesis. Any part played by drugs is uncertain. The crystals of lipid material are not unusual and have been seen in more than a third of twenty-nine consecutive marrow aspirates. It is possible that they have not been reported before because they are unimpressive when only a few are present or when viewed under low-power and they dissolve in immersion oil. In this patient, crystals were very numerous and associated with an accumulation of a substance containing neuraminic acid as demonstrated by thin-layer chromatography. It seems likely that the two are the same.

A ganglioside-like substance (haematocide) is found in the stroma of erythrocytes<sup>3</sup> and further work is being carried out to ascertain the nature of the substance containing neuraminic acid found in the bone marrow of our patient. It seems possible that its accumulation may have some bearing on inefficient haematopoiesis.

We thank Professor R. J. V. Pulvertaft for carrying out tissue cultures and Dr N. C. Allan for access to haematological records and for performing red cell survival studies.

**Addendum** (April 18, 1967). A similar observation has been made in an Irish woman, aged 28 years, with refractory anaemia. She was seen in April 1966 with severe pancytopenia and a hypoplastic bone marrow picture. She has been treated with prednisone, folic acid, vitamin B<sub>12</sub> and blood transfusions with no permanent alteration in the peripheral blood picture. In August 1966 she became pregnant. A bone marrow collected in February 1967 showed both hypoplastic fragments and

areas of myeloid hyperplasia with small groups of between three and five plasma cells. The plasma protein pattern was normal. A marrow collected on April 14, 1967, showed hypoplastic fragments. In addition, this marrow showed a crystalline deposit, identical in morphology and solubility properties to the crystal described previously.

### New Vasoconstrictor, Bovine Peptide B, released during Blood Coagulation

THE final stage of blood coagulation, the conversion of fibrinogen to fibrin by thrombin, is associated with the release of two acidic peptides designated A and B in the bovine system<sup>1</sup>. These peptides have been fully characterized by physico-chemical, chemical, and enzyme methods, and the exact amino-acid sequence has been determined<sup>2</sup>. Laki<sup>3</sup> has shown that the peptides released from fibrinogen affect the frog heart, and experiments carried out in this laboratory have shown that bovine peptide B (Fig. 1) in a concentration of  $4 \times 10^{-5}$  moles/l. produces a slow contraction of the rabbit carotid artery strip, while in a concentration of  $1.6 \times 10^{-6}$  moles/l. the peptide markedly potentiated the bradykinin-induced contraction of the isolated oestrous rat uterus. The present experiments were undertaken to ascertain whether bovine peptide B had any vasopressor effect *in vivo*.

Vascular responses were determined with a standardized bioassay technique in the rat previously described by Morris and Robinson<sup>4</sup>. In this bioassay, blood pressure in an anaesthetized rat chemically sympathectomized with pentolinium is measured by a mercury manometer connected to a carotid artery cannula. Increase in the blood pressure was measured after intravenous administration of angiotensin, oxytocin and bovine peptide B. The dose response for angiotensin is shown in Table 1. The mean increase in pressure elevation for a given dose is extremely reproducible and exhibits a small standard deviation ( $\pm 2.0$  mm of mercury). The maximum increase with intravenous angiotensin occurs in less than 1 min, and the blood pressure returns to the baseline in less than 3 min. The baseline pressure is constant within 2 mm for the duration of the experiments. The results of intravenous administration of bovine peptide B from three of the experiments are reported in Table 2. Peptide B for doses of  $4 \times 10^{-5}$ – $1.25 \times 10^{-2}$   $\mu$ moles gave a maximum increase in mean blood pressure of between 7 and 24 mm of mercury. The effect is approximately related to dose with insignificant effects noted at  $2 \times 10^{-5}$   $\mu$ moles and  $2.5 \times 10^{-2}$   $\mu$ moles and a broad maximum observed between  $8.0 \times 10^{-4}$   $\mu$ moles and  $6.2 \times 10^{-3}$   $\mu$ moles in these experiments.

Fig. 2. Rhythmic response of blood pressure in mm of mercury above stable baseline after injection of  $8 \times 10^{-4}$   $\mu$ moles of bovine peptide B.

Table 2 shows that bovine peptide B is more active as a vasopressor in small concentrations, while in high concentrations the vasopressor effect is markedly reduced. In all cases, the duration of the vasopressor lasted longer than 8 min, and was observed to be as long as 18 min. A typical response is illustrated in Fig. 2. The pressor effect, in addition to being prolonged, has a rhythmic variation and this has been observed in all experiments.

Table 1. BLOOD PRESSURE RESPONSE TO STANDARD DOSES OF SYNTHETIC VALINE 5-ANGIOTENSIN II IN TWENTY-FIVE RATS PREPARED BY STANDARD BIOASSAY

Injected dose of angiotensin (m $\mu$ g)	Measured blood pressure above baseline in mm of mercury	Range in blood pressure response in mm of mercury	Standard deviation
100	70-25	68-73	1.42
50	52-12	49-57	1.65
25	38-0	35-42	1.80
12.5	28-08	25-32	1.70
6.25	21-42	18-24	1.68
3.125	14-60	12-18	1.63
1.560	11-33	9-14	1.43
0.780	8-38	7-10	0.27

The prolonged vasopressor effect is unlike that of any other natural vasopressor peptide. Oxytocin is the only substance which approaches the length of vasopressor effect produced by bovine peptide B. Vasopressin and angiotensin have relatively short vasopressor effects—the entire response lasts less than 5 min. This suggests that bovine peptide B is not destroyed as rapidly as other natural peptide vasopressors. The slow disappearance of the vasopressor effect of bovine peptide B may result from the fact that the "active region" of this peptide is located at a distance from the carboxy and amino terminals and therefore is less susceptible to enzyme inactivation by exopeptidases. Binding of the bovine peptide B to smooth muscle could also decrease the rate of inactivation by enzymes. This prolonged effect *in vivo* would be analogous to the prolonged action on the contraction of uterus muscle of the rat by one of the human peptides released during the blood coagulation process. The "active site" of this peptide was determined to be a small fragment from the interior of the peptide molecule<sup>5</sup>.

Fig. 1. The primary structure of bovine peptide B.

Table 2. VASOPRESSOR EFFECT OF BOVINE PEPTIDE-B COMPARED WITH ANGIOTENSIN

Experiment	Sample	Dose ( $\mu$ moles)	Maximum blood pressure rise (mm of mercury)	Time of maximum blood pressure rise (min)	Duration of vasopressor response (min)
1	Angiotensin	$5 \times 10^{-4}$	54	0.58	2.0
	Angiotensin	$2.5 \times 10^{-4}$	40	0.66	1.8
	Angiotensin	$1.25 \times 10^{-4}$	27	0.75	1.7
	Peptide-B	$2.5 \times 10^{-4}$	2	4.00	-
	Peptide-B	$1.6 \times 10^{-4}$	10	4.00	> 15
	Peptide-B	$1.25 \times 10^{-4}$	18	2.25	> 15
	Peptide-B	$6.2 \times 10^{-5}$	20	7.00	> 15
	Peptide-B	$6.2 \times 10^{-5}$	24	6.50	> 15
2	Angiotensin	$5 \times 10^{-4}$	52	0.58	1.9
	Peptide-B	$4 \times 10^{-4}$	14	5.00	> 15
	Peptide-B	$4 \times 10^{-4}$	15	1.50	> 15
3	Angiotensin	$5 \times 10^{-4}$	51	0.66	2.0
	Peptide-B	$2 \times 10^{-4}$	5	1.00	8.5
	Peptide-B	$4 \times 10^{-5}$	7	2.00	10.0
	Peptide-B	$2 \times 10^{-4}$	8	0.66	9.0
	Peptide-B	$4 \times 10^{-4}$	11	5.00	12.0
	Peptide-B	$8 \times 10^{-4}$	17	1.50	> 15.0
	Peptide-B	$1.6 \times 10^{-4}$	13	7.00	14.5
	Peptide-B	$3.2 \times 10^{-4}$	11	6.00	8.0

Oxytocin produces vasoconstriction in the rat bioassay with a rise of 16 mm in blood pressure that lasts 9 min after a dose of  $3.5 \times 10^{-3}$   $\mu$ moles. The vasopressor effect of bovine peptide B in a dose of  $4 \times 10^{-4}$   $\mu$ moles produces in the same bioassay preparation a rise in the blood pressure of 14 mm mercury and will last longer than 15 min. While oxytocin produces a rhythmic contraction of the uterus<sup>6</sup>, it does not produce a rhythmic vascular response. Bovine peptide B is here shown to produce a rhythmic vasopressor effect on blood pressure.

While the concentrations of bovine peptide B which produce an *in vivo* response are large, they still represent the amount of peptide ( $4 \times 10^{-4}$   $\mu$ moles) expected to be liberated during the clotting of 1 per cent of the total fibrinogen in rat plasma. If intravascular clotting is a continuous process, then this amount of endogenous peptide could be in the circulation. The concentrations producing vasoconstriction are more appropriate to the expected concentrations locally in an injured tissue, thus suggesting that the material acts physiologically.

The mechanism of action of bovine peptide B in producing vasoconstriction is unknown. Whether it acts directly on the smooth muscle of the smaller blood vessels, or through potentiation of a second substance, has not been determined. The prolonged vasopressor effect of bovine peptide B may be an *in vivo* expression of the persistent action of this substance in potentiating bradykinin *in vitro*, presumably by attaching to some smooth muscle receptor. A third possible mechanism of action is a release by bovine peptide B of a second substance which is vasopressor in action; however, this seems to be the least likely possibility.

The results demonstrating the production of a prolonged rhythmic vasoconstrictor substance at the site of clot formation during the chemical processes of blood coagulation fit well with a postulate that it is an important part of local haemostasis. Teleologically, it is reasonable to expect a vasoconstrictor substance to be present during clotting of blood *in vivo*, because this action would decrease the flow of blood and effectively prevent the washing away of a partly formed clot. Bovine peptide B would then disappear after completion of clot formation, when it is presumed that clot protector vasoconstriction is not needed. Whether chronic tissue injury with production of small concentrations of circulating bovine peptide B vasopressor has a role in the production of chronic hypertension is unknown, but remains a possibility and needs future investigation.

In conclusion, a new vasopressor substance produced during blood clotting is described. The effect of intravenous injection of bovine peptide B is a prolonged rhythmic vasoconstriction and is unlike any previously described vasopressor peptide. The possible role of bovine peptide

B is postulated as assisting in local haemostasis by vasoconstriction.

## PATHOLOGY

### Induction of Tumours in Hamsters with Infectious Canine Hepatitis Virus

A NUMBER of adenoviruses which infect human beings and avian and other animal species have been shown to induce tumours in newborn golden Syrian hamsters. Included among these are several human adenoviruses<sup>1-3</sup>, chicken embryo lethal orphan (CELO) virus<sup>4</sup>, a number of simian adenoviruses<sup>5</sup>, and bovine adenovirus type 3 (ref. 10). We report here the induction of tumours in newborn hamsters by a canine adenovirus, the causative agent of infectious canine hepatitis (ICH). The tumour cells were shown to contain complement-fixing antigens for ICH virus.

Lederle strain 255 of ICH virus used in these studies was originally isolated in 1953<sup>11</sup> and was obtained from the American Type Culture Collection as third passage infected dog-liver suspension. A virus preparation (TCID<sub>50</sub>, titre 10<sup>7</sup>/ml.) was made by a single passage in canine kidney cells and inoculated into fourteen (three litters) newborn hamsters. Each hamster was inoculated with 0.1 ml. per site by intraperitoneal and subcutaneous routes.

Two of the fourteen inoculated hamsters developed 10-20 mm tumours at the site of inoculation, the first appearing on day 360 as a subcutaneous tumour and the

second as an intraperitoneal tumour on day 403. When the tumours reached a size of 30 mm (367 and 420 days after inoculation) they were surgically removed, minced to small pieces, and subcutaneously transplanted into newborn as well as weanling hamsters, most of which developed tumours (Table 1).

The serial subcutaneous transplants of the intraperitoneal tumour (hereafter referred to as IP line tumour) grew quite rapidly in newborn hamsters and reached sizes of 40 to 60 mm within 4–6 weeks, and the majority of these hamsters died within this time (Table 1). The growth of transplants in weanling hamsters was less rapid and some of the inoculated hamsters failed to develop tumours.

Grossly, the tumours were circumscribed pale grey masses containing small areas of haemorrhagic necrosis. The primary viral-induced subcutaneous tumour was a low grade fibrosarcoma which maintained its morphological characteristics on transplantation in hamsters. The primary intraperitoneal tumour was an undifferentiated neoplasm composed of sheets of large rounded to polygonal anaplastic cells with several foci of necrosis. Subcutaneous transplantation of this tumour through several hamster passages resulted in tumours which histologically resembled the primary intraperitoneal tumour, but which showed evidence of differentiation into whorls and bands of spindle cell sarcoma. In an occasional transplanted tumour the spindle cells were oriented about vascular

channels similar to the appearance of human adenovirus-induced hamster tumours. The basic cellular pattern was, however, that of spindle cell sarcoma in various stages of differentiation. Cell cultures established from the transplanted intraperitoneal tumour were of mixed epithelial and fibroblastic cell types. Hamster tumours induced by these cell cultures were morphologically similar to the primary viral-induced intraperitoneal tumour.

Attempts to isolate infectious ICH virus in canine kidney cells from clarified extracts of primary and transplanted tumours and tissue culture preparations of transplanted tumours repeatedly yielded negative results.

Hamsters developing large transplanted IP line tumours which survived beyond the fifth week usually developed complement-fixing serum antibodies which reacted with the homologous tumour antigen and with T antigens<sup>1,2</sup> of strain 255 and "Weybridge" strain\* of ICH virus prepared from infected canine kidney and ferret lung cultures (Tables 1 and 2). The antigen was present in titres of 1:16 to >1:80; the titre usually increased with the size and length of residence of the tumour in the hamster. Such complement-fixing antigens and antibodies were not detected in hamsters bearing the primary tumour or secondary transplants of the primary subcutaneous tumour.

The reactivity of the antigen and antibody described appeared to be specific for ICH hamster tumour system and ICH virus infected cultures; no cross reactions could be elicited with normal hamster tissue or canine kidney culture antigens or with heterologous hamster tumour antigens and antisera representative of those produced by human adenovirus types 7, 12, and 18, bovine adenovirus 3, SV<sub>40</sub>, polyoma, and Schmidt-Ruppin Rous sarcoma viruses. T antigens of human adenovirus types 7, 12, and bovine adenovirus 3 were similarly negative when tested with 4–8 units of complement-fixing antibodies from hamsters carrying the ICH virus-induced tumours<sup>5,10</sup>.

The specific reactivity of the latter sera with T antigens prepared from canine kidney cells infected with ICH virus is strong evidence that the hamster tumours observed were caused by ICH virus.

### Deposition of Glomerular Fibrin in the Rabbit after Infusion with Endotoxin

A WIDESPREAD deposition of fibrin in the renal glomeruli with subsequent necrosis of the renal cortex can be produced by two injections of endotoxin separated by 24 h. This mechanism of elucidation is called the (generalized) Sanarelli-Shwartzman phenomenon (SSP) (refs. 1 and 2). The single injection of endotoxin results in the deposition of glomerular fibrin in only 10 per cent<sup>3</sup> and necrosis of the renal cortex in 0.8 per cent<sup>4</sup> of the animals. In the pregnant rabbit at term, disseminated glomerular coagulation can be produced with great regularity by a single injection<sup>5</sup>, whereas fibrin thrombi in other organs, such as the heart and lung, can frequently be found after one injection<sup>6</sup>. It is believed that the time lag for deposition of fibrin in the kidney after two injections of endotoxin is essential for the SSP.

Bioassays for endotoxaemia<sup>7</sup> in patients with endotoxic shock indicated that circulating endotoxins are present for many days in these patients. It was therefore assumed that infusion with endotoxin would resemble human disease more closely than the SSP.

White albino rabbits weighing  $1.5 \text{ kg} \pm 200 \text{ g}$  were used. A polyethylene catheter was inserted through the ear vein into the superior vena cava<sup>8</sup>. Endotoxin *Escherichia coli* 025: B6 No. 462919 (Difco) was dissolved in 0.9 per cent saline (0.66 mg/100 ml.) and infused at a rate of 30–50  $\mu\text{g/kg/h}$  using a Buchler infusion pump. Blood was taken before and 2, 6, 10 and 14 h after infusion. The animals which did not die spontaneously during the experiment were killed at various times after infusion. Frozen sections (haematoxylin and eosin) as well as permanent (haematoxylin and eosin and periodic acid-Schiff) sections were prepared of liver, spleen, lungs, pituitary and kidney. The control group consisted of one single injection of 400  $\mu\text{g/kg}$  of endotoxin. Fibrinogen was assayed by the heat precipitation technique<sup>9</sup>. Platelets were counted in the phase contrast microscope using 'Unopette'<sup>2</sup>. For the thromboelastogram (TEG)<sup>10</sup> native blood was used.

The results are given in Table 1. Three control animals died spontaneously and two were killed after 6–8 h. No deposition of glomerular fibrin was found in this control group. Three animals had fibrin thrombi in the heart and lung.

In the infused group four animals died spontaneously between 0 and 6 h, and two were killed after 5 h. No fibrin was deposited in the kidneys. Twelve animals were killed or died between 8 and 14 h. All the animals of this group showed deposition of glomerular fibrin

Table 1. DISTRIBUTION OF GLOMERULAR FIBRIN DEPOSITION AND RENAL CORTICAL NECROSIS

	Injection; killed 6–8 h or died	Killed or died up to 6 h	Infused; killed or died between 8 and 14 h	Killed after 48 h	First kidney removed after 14 h	Second kidney removed after 48 h
Fibrin deposition	5/0	6/0	12/12	6/2	3/3	3/1
Cortical necrosis	5/0	6/0	12/1	6/2	3/0	3/1

and one had renal cortical necrosis. Six additional rabbits were killed after 48 h, 34 h after infusion for 14 h. Two of these animals showed severe renal cortical necrosis. Four animals showed no deposition of glomerular fibrin. This indicated lysis of the fibrin which was present before injection. In order to clarify this point, three animals were infused for 14 h after which the left kidney was removed under pentothal anaesthesia. Fibrin was deposited in the extirpated kidneys of these three animals whereas the remaining kidney of two rabbits obtained 34 h later was free of fibrin. One of these animals exhibited gross renal cortical necrosis after 34 h and moreover the fibrin was lysed.

Platelets in most of the infused group decreased in a straight line fashion to 10,000–30,000 c.c. Fig. 1 indicates the data in one animal representative for the whole group. The concentration of fibrinogen also fell and after 6–14 h it was not possible to coagulate the blood, as indicated in the TEG (Fig. 1).

These experiments indicate that deposition of glomerular fibrin and necrosis of the renal cortex can be reliably produced by intravenous infusion of endotoxin in rabbits, without a lag phase. The infusion with endotoxin resembles, so far as the widespread intravascular coagulation and the respective coagulation parameters are concerned, the infusion of thrombin in rats<sup>11</sup> and rabbits<sup>3</sup> as well as inhibitors of thrombin and protease<sup>12</sup>. The minimum time for the deposition of fibrin after infusion of this particular dose range seems to be 8 h because no animals below this infusion time showed glomerular fibrin. Platelets decreased more rapidly than fibrinogen. This agrees with previous data from Kliman and McKay<sup>13</sup>, who found that after thrombin infusion the concentration of fibrinogen rarely decreased to less than 80–100 mg per cent.

Renal cortical necrosis was defined by Margaretten *et al.*<sup>11</sup> as arising from glomerular thrombosis which persists long enough to produce necrosis of the renal cortex. The experiments on endotoxin infusion agree with this definition. Furthermore, the glomeruli in the group of animals developing renal cortical necrosis were

Fig. 1.

packed to nearly 100 per cent with fibrin (quantitative counting of involved glomeruli in per cent).

The four negative results in the group of animals killed after 48 h suggested that even the rabbit with its poor fibrinolytic system can lyse fibrin in the kidney after the infusion is ended. This suggestion was confirmed by the experiments in which one kidney was removed at the end of the endotoxin infusion, whereas the second kidney was obtained 34 h later after the animals had been killed. This agrees with a previous observation that glomerular fibrin produced by thrombin and protease inhibitors are lysed spontaneously after the inhibitor is metabolized from the tissue in the rabbit<sup>12</sup>. One animal which did show fibrin deposition after 14 h developed macroscopic renal cortical necrosis, but only very little fibrin was found at that time.

We suggest that this new experimental model of endotoxin infusion enables a continuous study of the biological events of endotoxaemia and the development of renal cortical necrosis as a pharmacological dose response reaction to be made.

### Toxicity and Teratogenicity of Optical Isomers of Thalidomide

THE thalidomide molecule contains an asymmetric carbon atom, but the form of the drug which has been used therapeutically and which has produced congenital malformations in man is the optically inactive form, that is ( $\pm$ )-thalidomide. The optical antipodes of thalidomide have been synthesized<sup>1,2</sup>, and Dr A. M. Creighton has supplied samples of both (+)- and (-)-thalidomide. The (+)-isomer, melting point 240°–241° C, showed  $[\alpha]_D^{20} + 60^\circ$  ( $c=2$  in dimethylformamide) and the (-)-isomer, melting point 241°–242° C, showed  $[\alpha]_D^{20} - 58^\circ$  ( $c=2$  in dimethylformamide). ( $\pm$ )-Thalidomide has a melting point of 271° C and, of course, is optically inactive. With these samples, we have determined the acute oral toxicities of the three forms in mice, their teratogenic activity in the New Zealand white rabbit and their effect on the hypnosis induced by hexobarbitone in mice.

Acute oral toxicities were determined by administering the compounds suspended in 1 per cent (w/v) carboxymethylcellulose in water to groups of twelve male SAS ICI albino mice (20–26 g body weight) and counting the mortalities after 24 h. The results (Table 1) show that the optically active isomers are much more toxic than the ( $\pm$ )-modification. After the administration of any one of the three forms at 0.25 g/kg, the mice were sedated but were capable of being aroused. With lethal doses of the

(+)- and (-)-isomers, however, depression of the central nervous system was severe and the mice died after 4–15 h.

The teratogenicity of the compounds was determined by administering them orally in a dose of 150 mg/kg daily from days 7 to 12 inclusive of pregnancy to New Zealand white rabbits. On day 28 of pregnancy the animals were killed and the resorption sites and normal and abnormal fetuses were counted. The types of malformations produced by the (+)- and (-)-isomers were similar to those found with the ( $\pm$ )-form<sup>3</sup> and, as Table 2 shows, all three modifications were teratogenic.

Table 1. ACUTE TOXICITY OF THE OPTICAL ISOMERS OF THALIDOMIDE IN MICE

Optical form	Oral LD <sub>50</sub> (g/kg)
( $\pm$ )	> 10.0
(+)	0.4
(-)	0.7

Table 2. TERATOGENICITY OF THE OPTICAL ISOMERS OF THALIDOMIDE IN NEW ZEALAND WHITE RABBITS

Optical form administered	No. of rabbits	Implantations	Resorptions	Normal fetuses	Malformed fetuses
None	5	42	3	39	0
( $\pm$ )	6	54	19	25	10
(+)	7	67	13	46	8
(-)	8	80	15	56	9

Table 3. EFFECT OF THE OPTICAL ISOMERS OF THALIDOMIDE ON THE TIME OF SLEEP INDUCED BY HEXOBARBITONE IN MICE

Optical form administered	Mean sleeping time min $\pm$ standard deviation
None	23 $\pm$ 7
( $\pm$ )	45 $\pm$ 9
(+)	43 $\pm$ 6
(-)	49 $\pm$ 8

( $\pm$ )-Thalidomide extends the time of sleep induced by hexobarbitone in rats<sup>4</sup>. This effect was examined in male SAS ICI albino mice with the three forms of thalidomide. The compounds (200 mg/kg) were administered orally to at least ten mice, 30 min before an intraperitoneal injection of 100 mg/kg of hexobarbitone sodium. The sleeping time was taken as the time between the loss and recovery of the righting reflex. Table 3 shows that any one of the three forms, in the conditions of the experiment, approximately doubles the sleeping time.

Thus, the three optical forms of thalidomide are teratogenic in the New Zealand white rabbit, are central nervous system depressants in mice, and are able to extend the time of sleep induced by hexobarbitone in mice. But the (+)- and (-)-isomers of the drug are much more toxic when given orally to mice than the ( $\pm$ )-form. The optically inactive form is known to be less soluble than the active isomers<sup>5</sup> and this could result in smaller concentrations in the blood. Crystalline ( $\pm$ )-thalidomide is probably a racemic compound and not simply a mixture or conglomerate of the two optical isomers. The physical properties of these isomers are being investigated.

## HAEMATOLOGY

Oxygen Binding by Haemoglobin J-Cape Town ( $\alpha_2$  92 Arg  $\rightarrow$  Gln)

AN abnormal haemoglobin with the electrophoretic mobility of a haemoglobin J has been found in Cape Town, South Africa, and subsequently shown to be  $\alpha_2$ (92 Arg  $\rightarrow$  Gln) $\beta_2$  (ref. 1). The oxygen binding characteristics of this new haemoglobin are of particular interest because haemoglobin J-Chesapeake, which has the substitution Arg  $\rightarrow$  Leu in the same position, has been shown to have an abnormally high affinity for oxygen<sup>2</sup>. Residue 92 of the  $\alpha$  chain occupies the position 4 in the non-helical sequence between the helical segments which have been denoted by F and G (ref. 3), and it is in this area that the  $\alpha$  and  $\beta$  chains are sliding past each other during oxygenation and deoxygenation of the haemoglobin molecule (personal communication from Perutz). A substitution of glutamine for arginine in this position can therefore be expected to influence the functional properties of the molecule and the haem-haem interaction.

Oxygen dissociation in haemolysates of blood containing haemoglobin A and haemoglobin J-Cape Town (35 per cent) is represented by Fig. 1. The slope  $n$  of the oxygen dissociation curve, which corresponds to the logarithmic form of Hill's empirical equation<sup>4</sup>, reflects haem-haem interaction. The figure also shows under the same experimental conditions data on fresh normal haemolysates, a normal control haemolysate from blood which was collected and transported from Cape Town to Cambridge at the same time as the A+J-Cape Town blood, and a fresh haemolysate of blood from a patient with haemoglobin A+haemoglobin J-Cambridge (50 per cent), the latter of which has its substitution in the periphery of the molecule<sup>5</sup>.

The oxygen dissociation curves were established on haemolysates of washed red cells diluted to a haemoglobin concentration of 200 mg per cent in 0.02 molar Sorensen phosphate buffer, pH 7.03, at 30° C. After washing with isotonic saline at 4° C, and lysing the erythrocytes with four volumes of chilled water, the red cell ghosts were removed by centrifugation at 22,000g for 45 min at 0° C. The oxygen dissociation curves were determined by the

tonometric procedure adapted from that used by Allen, Guthe and Wyman<sup>6</sup>; the measured volumes of moist air were admitted to the tonometer from a mercury meniscus pipette similar to that of Rossi-Fanelli and Antonini<sup>7</sup>. The tonometers used were all glass and designed to fit in the Unicam SP800 recording spectrophotometer, and had a 10 mm light path cuvette attached with a nominal capacity of 100 ml. The percentage saturation of the haemoglobin with oxygen was calculated by comparing the optical densities of fully oxygenated and fully deoxygenated with the partially oxygenated sample at a fixed wavelength near the maximum of the oxyhaemoglobin  $a$  absorption band (577 m $\mu$ ). The oxygen tension at each point on the curve was calculated from the volume and temperature of the air in the tonometer, and the volume, temperature, pressure and humidity of air admitted from the pipette (assuming partial pressure of oxygen in air to be 20.95 per cent). The amount of oxygen dissolved in the haemoglobin solution and that bound to haemoglobin was neglected in the calculations, for it was only about 0.1 per cent of the total present. Absorption spectra from 700–450 m $\mu$  were drawn of every specimen in the fully oxygenated state before and after each investigation to ensure that no methaemoglobin had formed and no other spectral change had occurred during measurement. The reproducibility of the method was within 1 per cent.

The control blood collected and transported with the A+J-Cape Town specimen showed, in the first place, no spectral or electrophoretic evidence of ageing and, when the oxygen dissociation curve was determined 2 days after the blood had been drawn, there was no significant difference between it and that of fresh haemolysates. The haemoglobin A+J-Cape Town haemolysate, however, which was examined only 1 day after it had been drawn, showed an increased oxygen affinity and the  $n$  value was 1.9 compared with 2.6 for normal haemolysates.

The change of oxygen affinity with pH—the Bohr effect—was found to be the same for the A+J-Cape Town haemolysate and normal haemolysate at 50 per cent saturation. For the mixed haemoglobin, however, the oxygen pressure was 0.13–0.14 mm of mercury less than in the normal haemolysate at each pH investigated (Table 1).

Table 1. BOHR EFFECT IN HAEMOGLOBIN J-CAPE TOWN, USING PHOSPHATE BUFFER 0.02 MOLAR AT 30° C

Haemolysate	pO <sub>2</sub> (mm of mercury) at 50 per cent saturation pH 6.41	pH 7.03	pH 7.80
Normal	1.31	0.95	0.52
A+J-Cape Town	1.18	0.81	0.39

Fig. 1. Log plot of oxygen dissociation curves from J-Cape Town fresh whole haemolysate and controls.  $\Delta$ , J-Cape Town whole haemolysate;  $\blacktriangle$ , normal from Cape Town whole haemolysate, fresh;  $\circ$ , J-Cambridge whole haemolysate, fresh;  $+$  and  $+$ , normal whole haemolysates, fresh.

Charache *et al.*<sup>2</sup> have shown that the  $n$  value of the whole blood containing 30 per cent haemoglobin Chesapeake is 1.8 and mention that haemolysates also showed this smaller  $n$  value. The  $n$  value for whole blood haemolysate containing 35 per cent haemoglobin J-Cape Town was found to be similarly small, namely, 1.9 in our conditions. The altered oxygen binding by haemoglobin J-Cape Town ( $\alpha$  92 arginine  $\rightarrow$  glutamine) and presumably also that by haemoglobin Chesapeake ( $\alpha$  92 arginine  $\rightarrow$  leucine) are not merely the outcome of an additional negative charge in each half molecule. This can be concluded from the normal results with haemoglobin J-Cambridge which also has one negative charge more in each half molecule than haemoglobin A. It seems that the alteration in oxygen binding is related to the position of the amino-acid substitution in an area of the  $\alpha$  chain- $\beta$  chain contact within the haemoglobin molecule. The arginine residue of the normal  $\alpha$  chain which is replaced by a residue of leucine in haemoglobin Chesapeake and by one of glutamine in haemoglobin J-Cape Town is found in the  $\alpha$  chain of all mammalian haemoglobins so far investigated. It is not present in the haemoglobin of lamprey and in sperm whale myoglobin where there is no diversity of peptide chains and hence no interaction between unlike chains.

We thank Dr M. C. Botha and Dr H. Lehmann for the blood samples and for advice.

### Effect of Catecholamines on Platelet Aggregation caused by Thrombin

THE addition of thrombin to human blood platelets results in their rapid aggregation, with release of 5-hydroxytryptamine and adenine nucleotides<sup>1</sup>. Whether thrombin-induced platelet aggregation is produced solely by adenosine diphosphate (ADP) released from the platelets or whether thrombin also has a direct aggregating effect is still not clear<sup>2,3</sup>. The aggregation by adrenaline or ADP of human platelets occurs in two phases, and it has been suggested that the second phase is brought about by ADP released from the platelets<sup>4</sup>. The second phase of platelet aggregation caused by ADP is inhibited by chlorpromazine and similar drugs, and potentiated by adrenaline<sup>5,6</sup>. Platelets are known to contain small amounts of catecholamines<sup>7,8</sup>. The evidence reported here suggests that sufficient catecholamines are released from the platelets during aggregation by thrombin to potentiate aggregation.

Blood was obtained from the antecubital vein of healthy volunteers. The blood was collected in plastic centrifuge tubes containing 10 per cent by volume of a 3.8 per cent solution of trisodium citrate, and centrifuged for 10 min at 220*g* at room temperature. The platelet-rich plasma was kept in plastic containers at room temperature and used within 3 h. Platelet aggregation was measured using the turbidimetric method of Born<sup>9</sup> as modified by Mills and Roberts<sup>5</sup>. A 1-ml. sample of platelet-rich plasma was pre-warmed to 37° C for 5 min in a transparent plastic tube and then placed in a constant temperature cell compartment in the modified EEL titrator. The plasma was stirred from below with a magnetic stirrer. Light transmission was recorded continuously on a 1-mV recorder at a chart speed of 2.5 cm/min. The recorder scale was calibrated by setting the titrator to 100 per cent transmission with each platelet-free plasma and adjusting the scales to give full-scale deflexion between 10 and 60 per cent. Reagents were added with microsyringes in volumes of up to 30  $\mu$ l.

Superimposed aggregation traces of platelet-rich plasma with varying doses of thrombin are shown in Fig. 1. A small increase in dose converted reversible aggregation into a second phase of aggregation which was irreversible. The critical concentration of thrombin at which the second phase of aggregation occurred varied from one donor to the next. With the concentrations of thrombin used, the plasma did not clot within the 4-min period of observation. Platelet aggregation could be separated into two distinct phases in seventeen of twenty-two plasma samples tested; in the remaining five samples, it was not possible to demonstrate this separation.

Fig. 1. Aggregation by thrombin of platelets in human citrated platelet-rich plasma. Thrombin was added at the arrow to give the final concentrations (N.I.H.  $\mu$ /ml.) shown by each curve.

The addition of low concentrations ( $10^{-8}$ – $5 \times 10^{-8}$  moles/l.) of adrenaline to platelet-rich plasma did not result in aggregation. Such concentrations of adrenaline, however, markedly potentiated the aggregation brought about by thrombin. As shown in Fig. 2,  $2 \times 10^{-8}$  moles/l. adrenaline pre-incubated for 1 min with platelet-rich plasma changed reversible first-phase aggregation into irreversible second-phase aggregation. While the potentiating effect of adrenaline was seen primarily in its ability to evoke the second phase, adrenaline also slightly increased the speed of the first phase. Aggregation by thrombin was also potentiated by noradrenaline, but its effectiveness was between two and three times less than that of adrenaline.

The effects of adrenergic blocking agents on thrombin-induced aggregation were then examined. With a dose of thrombin sufficient to evoke the second phase, the  $\alpha$ -blockers phentolamine and dihydroergotamine, added at 1–2  $\mu$ moles/l. 1 min before the thrombin, prevented development of the second phase (Fig. 3). The  $\beta$ -blocker

Fig. 2. Potentiation by adrenaline of platelet aggregation induced by thrombin. Thrombin was added at the arrow to give a final concentration of 0.2  $\mu$ /ml. Adrenaline (Ad) was added one minute before thrombin to give the final concentrations shown by each curve.

Fig. 3. Inhibition by phenolamine (Ph) and tyramine (Ty) of platelet aggregation induced by thrombin. Thrombin was added at the arrow to give a final concentration of 0.2 u/ml. Phenolamine (2  $\mu$ moles/l.) was added 1 min before thrombin, and tyramine (100  $\mu$ moles/l.) was incubated for 20 min at 37° C before adding thrombin.

propranolol had no effect on second phase aggregation at 2–5  $\mu$ moles/l. but inhibited it at 10  $\mu$ moles/l. It appeared therefore that propranolol could inhibit second phase aggregation, but less effectively than  $\alpha$ -blockers.

These observations suggested that thrombin was releasing sufficient catecholamines from the platelets to potentiate aggregation. Tyramine displaces catecholamines from various tissues and also 5-hydroxytryptamine from platelets<sup>10</sup>. The effect of pre-incubating platelets with tyramine was therefore examined. In fresh plasma, 100  $\mu$ moles/l. tyramine, added 20 min before thrombin, inhibited its ability to produce the second phase (Fig. 3). After 20 min pre-incubation the second phase was not blocked by tyramine at 20  $\mu$ moles/l. whereas 1 mmole/l. blocked after only 10 min.

Aggregation by ADP is potentiated by 5-HT<sup>11</sup>. Because thrombin releases 5-HT from platelets<sup>1</sup>, it is possible that the potentiating effects observed were due to released 5-HT rather than catecholamines. The specific 5-HT antagonist methysergide, at 2–5  $\mu$ moles/l., had no effect, however, on second phase aggregation caused by thrombin. In contrast, desmethylinipramine inhibits second phase aggregation by ADP without affecting the first phase<sup>5</sup>. It was found similarly that second-phase aggregation by thrombin could be inhibited by 20  $\mu$ moles desmethylinipramine, but first-phase aggregation could not.

The dose of thrombin required to demonstrate these effects was critical. On one hand, sufficient thrombin had to be added to induce the second phase of aggregation. On the other hand, too large a dose of thrombin produced rapid and irreversible aggregation, with subsequent clotting, and the effects of adrenergic blocking agents were obscured. The observations can be explained by assuming that thrombin releases catecholamines from platelets, which then either potentiate the aggregating action of thrombin itself or that of the ADP released by thrombin, or both. It has already been shown that exogenous catecholamines powerfully potentiate the aggregating action of ADP and thrombin<sup>6,11,12</sup>. Catecholamines are concentrated in platelets<sup>13</sup> although the amounts differ according to various reports. Pig platelets contained 0.2–2.6 ng adrenaline/10<sup>8</sup> platelets<sup>7</sup>. Human platelets contained 0.2–0.7 ng catecholamines/10<sup>8</sup> platelets<sup>14</sup>, or an average of 0.8 ng/10<sup>8</sup> platelets<sup>8</sup>. The number of platelets in 1 ml. of platelet-rich plasma (about 4  $\times$  10<sup>9</sup>)

therefore contain 1–3 ng catecholamines. Assuming that thrombin releases most of this from the platelets, the concentration of adrenaline in the plasma is similar to that which has to be added to potentiate aggregation (10<sup>-8</sup> moles/l. = 2 ng/ml.). It seems reasonable therefore to suggest that the aggregation of platelets can be potentiated by their own catecholamines, if released.

The release of catecholamines from platelets by degranulating agents such as thrombin and collagen may therefore play an important part in determining the extent of the reaction of platelets to such agents. It suggests that the contents of the platelets markedly affect their function in haemostasis and thrombosis.

I thank Professors G. V. R. Born, D. C. B. Mills and G. C. K. Roberts for helpful advice and criticism. ### Erythrocyte Glucose-6-phosphate Dehydrogenase Deficiency in Uganda

DEFICIENCY in erythrocyte glucose-6-phosphate dehydrogenase (G-6-PD) has been found to be widespread in the tropics and sub-tropics<sup>1-9</sup> as well as in the Negro population of America<sup>10</sup>. Surveys of G-6-PD deficiency in limited areas and populations in Uganda have been reported before<sup>11-13</sup>, but no country-wide screening for this deficiency in Uganda has been published. In the present investigation only African males were tested, by a screening test with the reduction of brilliant cresyl blue (National Aniline Division) as indicator<sup>14</sup>. The results, which are shown in Table 1, agree in general with findings in other countries, as well as with the 15 per cent prevalence in Kampala<sup>11</sup>. The low prevalence in Kabale, however, is striking and compares with that of 2 per cent found in South African male Bantu<sup>15</sup>. Kabale, at an altitude of 6,000 ft., is situated in the highlands of Kigezi in South-West Uganda near the Rwanda border, and the prevalence of malaria there has been very much lower than elsewhere in Uganda. Conversely, endemic malaria is known to be more prevalent in Bundebugyo than elsewhere<sup>16</sup>, and Lehmann and Raper<sup>16</sup> found there the exceptionally high sickling rate of 39 per cent. The prevalence of G-6-PD deficiency in Bundebugyo, which is slightly greater than average, was shown by tests made on a mixture of indigenous males and recent immigrants from the Fort Portal region. The prevalence among the people indigenous to Bundebugyo region may be considerably greater.

Table 1. PERCENTAGE OF MALES IN VARIOUS PARTS OF UGANDA WITH GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENCY OF THE RED CELLS

Town	No. tested	No. of abnormals	Percentage of abnormals
Fort Portal	100	11	11
Bundebugyo	65	12	18
Kabale	180	5	3
Mbarara	100	9	9
Mbale	100	14	14
Soroti	100	13	13
Moroto	60	8	13
Gulu	100	12	12
Aura	67	6	9

These findings support the theory of a connexion, direct or indirect, between G-6-PD deficiency and malaria<sup>17</sup>.

### Protein Synthesis in Leucocytes of Diabetic and Normal Subjects

THERE are some indications that diabetes mellitus is a disease involving a disorder of carbohydrate, lipid and protein metabolism. Leucocytes possess a nucleus and mitochondria, and metabolize glucose, amino-acids and fatty acids, and therefore might be useful for the investigation of certain aspects of metabolism in human diabetes. Investigation of glucose uptake and oxidation, lipid metabolism and lactic acid formation in leucocytes has had varied results<sup>1-3</sup>. Protein synthesis has not been investigated in leucocytes, and we aimed to determine the differences in protein metabolism in leucocytes from control and diabetic patients.

Six diabetic patients who required insulin or oral anti-diabetic agents were examined. Their fasting blood sugar concentration was 100–180 mg/100 ml. After treatment with insulin for 24 h or an oral antidiabetic agent, heparinized blood was added to a tube containing dextran, to give a final concentration of dextran of 1 g/100 ml. This tube was refrigerated at 5°C for 45 min. After sedimentation of erythrocytes the supernatant was transferred into another tube and the suspension contained 10<sup>4</sup> leucocytes/ml.

To 0.2 ml. of leucocyte suspension was added radioactive glycine or cysteine in 0.5 ml. of buffer. The specific activity for cysteine was 9 mc./mmole and glycine 17 mc./mmole. The cysteine had an activity of 0.1 µc./ml. and the glycine of 0.5 µc./ml. The tubes were incubated for 120 min at 37°C. At the end of the incubation the leucocytes were washed twice with 10 per cent trichloroacetic acid. Radioactivity was determined with a gas flow counter in the case of radiocarbon, and with a Geiger-Müller thin-window tube in the case of cysteine.

The protein content was determined by the ninhydrin method. Samples of 1 ml. of blood from some patients was incubated with cysteine. In each experiment, both diabetic and control leucocytes were investigated. The chemicals used were pure.

The incorporation of glycine-1-<sup>14</sup>C and cysteine-<sup>35</sup>S by leucocytes from control and diabetic subjects is interesting. Comparison of the protein synthesis of control and diabetic leucocytes shows an increased protein synthesis in leucocytes from diabetic subjects (Table 1). The incorporation of labelled glycine into the protein fraction in the diabetic patients was three times that of normal controls. There was less incorporation of cysteine, but it was still very significant.

Table 1. INCORPORATION OF LABELLED GLYCINE AND CYSTEINE INTO THE PROTEIN OF LEUCOCYTES FROM NORMAL AND DIABETIC SUBJECTS

Test	Subject	Glycine-1- <sup>14</sup> C		Cysteine- <sup>35</sup> S	
		mg N	C.p.m.	C.p.m./mg N (specific activity)	C.p.m. × 10 <sup>3</sup> / mg N (specific activity)
Leucocyte suspension	Control	4.1	4,338	1,058	61.2
		4.0	1,478	369	68.9
		4.1	2,455	598	59.1
		3.9	1,704	437	110.9
	Mean value	4.0	2,493	615	75.3
Leucocyte suspension	Diabetic	4.6	6,495	1,412	120.8
		4.5	12,239	2,719	142.5
		4.6	5,050	1,097	103.9
		4.2	9,804	2,334	151.6
	Mean value	4.5	11,842	2,632	152.3
Whole blood	Control	1.5	—	—	43.2
Whole blood	Diabetic	1.5	—	—	54.9

When whole blood was used instead of leucocytes, there was more protein synthesis in the diabetics than in the controls, as indicated by the uptake of cysteine. Measurement of protein synthesis employing these two amino-acids gave varying results in the leucocytes from different patients, but the differences between normals and diabetics were still significant.

To find out about increased protein synthesis in leucocytes of diabetics we examined the effect of glucose in different concentrations. Leucocytes from controls were stored at increasing concentrations of glucose for 8 h and were incubated with cysteine-<sup>35</sup>S (Fig. 1). The results show that the protein synthesis of normal leucocytes depends on the concentration of glucose present.

These findings demonstrated that in every case the protein synthesis by leucocytes of diabetic subjects was significantly greater than the controls. In interpreting our results it might be supposed that the greater concentration of glucose caused increased protein synthesis in normal patients, for they suggest that the greater protein synthesis in diabetic leucocytes is also caused

Fig. 1. Effect of glucose concentration on the cysteine incorporation into the protein fraction of leucocytes from normal subjects.

by the metabolic effect of glucose and not necessarily by the diabetic process itself.

## PHYSIOLOGY

### Transmission of Receptor Potential in Dipteran Chemoreceptors

THE structure of the contact chemoreceptor sensilla on the labellum of certain muscid diptera has been studied by light<sup>1,2</sup> and electron<sup>3,4</sup> microscopy, but little attempt has hitherto been made to relate this structure to possible electrical phenomena within the receptor.

Morita and Tateda<sup>5</sup> and Wolbarsht and Hanson<sup>6</sup> have shown that the site of generation of action potentials is located in the region of the cell bodies of the receptor neurones proximal to the base of the receptor shaft and separated by as much as 500 $\mu$  from the distal tip of the sensilla to which the chemical stimulus is applied. There is no evidence for the generation of action potentials at the tip of the receptor shaft. Morita and Yamashita<sup>7</sup> showed that a slowly declining potential difference is established across the terminal membrane of the sensory dendrite when the tip is stimulated with water or aqueous solutions of sucrose or sodium chloride, such that the inside of the receptor membrane becomes positive relative to the outside. These distal potential changes must be transmitted to the site of generation of action potentials according to the cable properties of the sensillum.

The shaft of the sensillum contains two cuticular lumina, one large, thin walled and crescentic in the transverse section and one smaller, thick walled and circular in outline<sup>1,3</sup>. Larsen also showed that the distal dendrites of the receptor neurone fill the smaller lumen almost completely (Fig. 1a). The larger lumen communicates directly with the vacuole of the trichogen cell; this vacuole invests the proximal extensions of the smaller lumen wall (termed the scolopoid body by Stürckow<sup>2</sup> and Larsen<sup>3</sup>) which, in turn, surrounds the sensory dendrites just after they emerge from the cell body (Fig. 1b). Examination of Larsen's electron micrographs shows a transition from the thick wall of the small lumen (thickness 1.5 $\mu$ ) through the characteristically plicate section of the

(c) Diagram to show the predicted pathway of the principal depolarizing current in the contact chemoreceptor of the labellum of muscid diptera. The pathway is shown by arrows. *l*, Large lumen; *s*, small lumen almost filled by receptor dendrites; *st*, stimulus solution; *sc*, scolopoid body; *e*, extension of scolopoid body; *n*, receptor neurone cell body; *v*, trichogen cell vacuole; \*, probable coincident location of the generator potential and the site of initiation of action potentials. Cuticle is shown stippled and the discontinuity in the receptor shaft (indicated by dashed connexions) is included for convenience in drawing. The separation of receptor tip and base may exceed 300 $\mu$ .

scolopoid body, with thinner walls, to separate tubular extensions formed by the closure of the lobes of the scolopoid body surrounding the sensory dendrites. In this latter region the walls have decreased in thickness to approximately 500 Å.

Longitudinal electrotonic transmission of the slow potential changes from the distal extremity to the basal regions of the sensillum cannot occur except in the presence of two conducting pathways separated by an insulator of relatively high resistance. Fig. 2 is a diagram of two alternative pathways of current flow which might account for the electrotonic transmission. In both cases one pathway must be the cytoplasm of the receptor dendrite; the return current might flow in the space between the dendrite and the wall of the small lumen (Fig. 2b) or through the contents of the large lumen (Fig. 2a). In *Phormia*, Larsen<sup>3</sup> has demonstrated a very restricted space between the receptor dendrite and the inner wall of the small lumen with a maximum thickness of 1500 Å. In *Stomoxys*, a closely related species of fly, Adams and Holbert<sup>4</sup> were unable to show such a space. There can be no doubt that the large lumen exists.

In the basal region of the receptor shaft maximal current flow between the dendrite cytoplasm and the

contents of the large lumen might be expected in any plane normal to the long axis of the receptor shaft at which the scolopoid body and its proximal extensions run through the trichogen cell vacuole. This vacuole has been shown to communicate directly with the contents of the large lumen (ref. 3 and Tominaga, Y., personal communication), and to be filled with material of similar appearance under the electron microscope. The generation site of action potentials is situated at about the same position as any of these planes of section<sup>5</sup>.

In electrotonic transmission, the relationship  $V_x = V_0 \cdot e^{-x/\lambda}$  may be used to describe the voltage attenuation—length characteristics of a bifilar conductor system, where  $V_0$  is the potential applied between the two conductors,  $V_x$  the potential measured between the two conductors in a plane normal to the longitudinal axis of the cable at a distance of  $x$  cm from the plane of application of  $V_0$  and where  $\lambda$  is the length constant of the cable.  $\lambda$  can be shown to equal  $(r_m/r_o + r_i)^{1/2}$ , where  $r_m$  is the transverse resistance  $\times$  unit length of the insulator between the two conductors measured in ohm cm, and  $r_o$  and  $r_i$  represent the resistances per unit length of the two conductors (in ohm cm). If  $r_m$  is increased,  $\lambda$  will increase with accompanying decrease in cable voltage attenuation, but if either  $r_o$  or  $r_i$  is increased,  $\lambda$  will decrease, resulting in greater voltage attenuation.

The diagrammatic structures shown in Figs. 2a and 2b may be discussed in relation to these properties. If the receptor dendrites are separated from the inner wall of the small lumen by a fluid layer forming the second longitudinal conductor,  $r_m$  becomes a parameter of the dendrite membrane alone (Fig. 2b). In Fig. 2a where the second longitudinal conductor is formed by the contents of the large lumen,  $r_m$  describes the series resistance of both dendrite membrane and a thickness of cuticle. Clearly,  $r_{m(a)} \gg r_{m(b)}$ . Further, the longitudinal resistance of a restricted fluid layer only 1,500 Å thick is likely to be much greater than that of the contents of the large lumen: ( $r_{o(a)} < r_{o(b)}$  in Fig. 2). Hence electrotonic transmission is attended by smaller cable losses in the network of Fig. 2a than that of Fig. 2b.

It is therefore suggested that the main depolarizing current of the site of generation of action potentials in dipteran chemoreceptors of this type may follow the pathway shown by arrows in Fig. 2c. In this system a Nernst potential set up across the membrane of the distal tip of the receptor dendrite drives a current through the dendrite cytoplasm, the dendrite membrane at the action potential initiation site, the attenuated wall of the proximal extension of the scolopoid body, the trichogen cell vacuole and the contents of the large lumen back to the membrane of the tip of the dendrite. The insulator allows little current to flow between the large and small lumina of the receptor except in the region where action potentials are initiated (the site of the generator potential). It is not yet known whether the application of the stimulating solution provides the final link in this current pathway, or, if this link is pre-existent, whether such an application merely establishes the receptor potential.

## Sensitivity of L Cells in Exponential and Stationary Phase to 5-Fluorouracil

ANTICANCER agents have recently been classified according to their lethal effects on normal murine haematopoietic and lymphoma spleen colony-forming cells<sup>1</sup>. The members of one class, which includes 5-fluorouracil, reduce the survival *in vivo* of actively dividing lymphoma cells by a far greater degree than that of normal haematopoietic cells which are presumed to be in a resting state. When these two cell types were treated with 5-fluorouracil *in vitro* and assayed *in vivo*, a similar difference in survival was noted<sup>2</sup>. It was proposed that this difference in sensitivity is a consequence of the difference between the proliferative states of the two cell types<sup>1,2</sup>. In order to test this hypothesis and to establish a model system *in vitro*, the sensitivity of mouse L cells to 5-fluorouracil was determined by the colony formation method of Puck *et al.*<sup>3</sup>, either when the cells were in a rapidly proliferating state (exponential phase) or when they were in a non-proliferating state (stationary phase). Few reports of the survival of the colony forming ability of mammalian cells *in vitro* following exposure to chemotherapeutic agents have been published and in only one instance has the lethal effect of 5-fluorouracil been described in such a system<sup>4</sup>.

Mouse L cells (strain L60) were grown as suspension cultures in medium No. CMRL 1066<sup>5</sup>, from which nucleosides and coenzymes were omitted. The medium was supplemented with dialysed foetal calf serum at a concentration of 10 per cent. The serum was dialysed against phosphate buffered saline solution, volume ratio 1:20, for 24 h three consecutive times in order to remove nucleosides, which might affect the action of 5-fluorouracil from the serum. Cells from a stock bottle were diluted and 9.5 ml. of the cell suspension dispensed into each of a series of plastic test-tubes (Falcon Plastics, California) at a concentration of about  $4 \times 10^4$  cells/ml. The tubes were placed in a roller wheel and incubated at 37°. Fig. 1 shows a growth curve for cells grown under these conditions. Cells were treated with 5-fluorouracil on the first and second days after dilution into tubes (exponential

Fig. 1. Growth curve for mouse L cells in suspension culture. Arrows denote treatment times, see text and Fig. 2. Open arrows, exponential phase; closed arrows, stationary phase. The doubling time was 17 h.

Fig. 2. Survival curves for mouse *L* cells exposed to 5-fluorouracil for 1 h *in vitro*. Open symbols, cells treated in the exponential (log) phase of the growth cycle (plating efficiency = 80 per cent;  $C_{10} = 6 \mu\text{g/ml.}$ ); closed symbols, cells treated in the stationary phase (plating efficiency = 50 per cent;  $C_{10} = 18 \mu\text{g/ml.}$ ). Triangles and circles represent treatment at different times within the given phase of the growth cycle, as denoted by the arrows in Fig. 1.

phase) and on the fourth and fifth days (stationary phase) as indicated by the arrows in Fig. 1. One half ml. of graded concentrations of the drug was added to the tubes, which were then returned to the incubator for 1 h. After this interval, the cells were spun down in a clinical centrifuge, the medium decanted and the cells resuspended in fresh medium. After appropriate dilutions, the cells were plated into Petri dishes, 5 per point, containing medium supplemented with undialysed serum. The number of cells added per dish was adjusted to give about 100 colonies per dish. After 14 days of incubation at  $37^\circ$  in a humidified atmosphere of 5 per cent carbon dioxide and 95 per cent air, the colonies were stained with methylene blue and counted. The survival curves thus determined are shown in Fig. 2.

The survival curves exhibit small shoulder regions and are similar to radiation survival curves. The  $C_{10}$ , that is the concentration of the drug required to reduce the survival to 10 per cent on the exponential region of the curve, was  $6 \mu\text{g/ml.}$  for exponential phase cells at both times examined. The  $C_{10}$  for stationary phase cells was  $18 \mu\text{g/ml.}$ , also at both times examined. It is clear that the rapidly dividing exponential phase cells were three times as sensitive to 5-fluorouracil, over the range of doses examined, as were the stationary phase cells.

To check that the stationary phase cells were not proceeding around the mitotic cycle, cells in either the exponential or stationary phase were exposed to  $^3\text{H}$ -thymidine for 1 h. Autoradiographic preparations showed that while 45 per cent of exponential phase cells were labelled, essentially none of the stationary phase cells was labelled. Thus the stationary phase cells did not proceed through the DNA synthetic phase of the mitotic cycle.

Because the cell concentration in the stationary phase was up to five times that in the exponential phase, the possibility that the drug was exhausted by the stationary phase cell population was examined. Cells in either phase were incubated with  $^3\text{H}$ -5-fluorouracil for 1 h and it was found that less than 0.01 per cent of the drug present in the medium was incorporated in either case.

The  $C_{10}$  values for mouse *L* cells may be compared with those for murine lymphoma cells and normal haematopoietic cells ( $C_{10} = 3.3$  and  $22.5 \mu\text{g/ml.}$  respectively), also exposed to 5-fluorouracil for 1 h *in vitro* (calculated from ref. 2). The difference in sensitivity to 5-fluorouracil between exponential and stationary phase *L* cells, although not as marked as that between murine lymphoma and normal haematopoietic cells, supports the hypothesis that the action of this drug depends on the proliferative state of a cell population. These results are in agreement with the observations of Bhuyan *et al.*, who reported that 5-fluorouracil had no detectable effect on resting human *KB* cells in tissue culture, as tested by a collagen plate assay, but did show a marked cytotoxicity to rapidly dividing *KB* cells tested by a broth dilution assay<sup>6</sup>. Our results also suggest that an *in vitro* colony-forming system may be utilized as a screening procedure for drugs which selectively destroy rapidly dividing cells.

Further interpretation of survival data for cells exposed to 5-fluorouracil *in vitro* is complicated by the fact that more recent work, to be described in a later publication, has shown that the survival of *L* cells exposed to 5-fluorouracil is affected by the presence of nucleosides in the medium, both before and after treatment. This effect may be evinced by the use of different batches of serum to supplement the medium, especially if the serum has not been dialysed.

### Tritiated Water Space in Gastrocnemius of Rat

If a muscle is heated at  $105^\circ\text{C}$  until its weight is constant, the loss in weight (70–80 per cent of the original weight) represents the total amount of water in the muscle. More refined methods of estimating water contained in the tissue—normally applied to a whole animal *in vivo*—have been evolved; these methods depend on the equilibration of a marker molecule within the fluid spaces of the tissue or tissues under examination, followed by subsequent estimation of its concentration therein. The use of various markers, notably urea, thiourea and sulphanilamide, and their degree of correspondence with whole body water content as obtained by desiccation, has been comprehensively reviewed by Keys and Brozek<sup>1</sup>. Antipyrine spaces have been found to agree with tissue deuterium oxide spaces<sup>2</sup> and tritiated water spaces<sup>3</sup>. Antipyrine, however, is slowly metabolized<sup>4</sup>, and, like its *N*-acetyl-4-amino-derivative<sup>5</sup>, equilibrates relatively slowly with tissue fluids. Neither of these disadvantages is found in the case of deuterium oxide<sup>6</sup> or tritiated water<sup>3</sup>, although a small rapid exchange has been noted between the isotopic hydrogen atoms and the hydrogen atoms in the organic molecules of the tissues<sup>3,7</sup>.

Overton<sup>8</sup> considered that a fairly extensive proportion of the water in muscle is osmotically bound; that is, it is unable to participate in the normal osmotic exchanges of tissue fluid. Such water would not therefore be expected to take part in equilibration exchanges with the osmotically active markers referred to here, although it might be able to do so with deuterium oxide or tritiated water. Hill<sup>9</sup>, while confirming the experimental evidence on which Overton's deductions were based, suggested alternative explanations for them which are physiologically more reasonable, and doubted whether a significant proportion of muscle water was "bound". The present work was undertaken to assess not so much whether any muscle water is rigidly "bound", but whether there may be some proportion of it which might fail to equilibrate with marker molecules within a time sufficient for equilibration to occur between the marker and the majority of the tissue water. A non-osmotic marker, tritiated water, was used; this has the advantage of not being subject to any possible inequalities of distribution from Donnan effects. The investigation was confined to a single muscle, the gastrocnemius of the female rat.

The marker was introduced into the whole hind limbs of the rats by a perfusion technique already developed for other similar investigations<sup>10,11</sup>. It is felt that this method of perfusion permits thorough irrigation of the muscle vasculature, although because of employment of sub-physiological perfusion pressure, the attainment of equilibration is a more prolonged process than would be expected under completely physiological conditions.

Proteinized Ringer's solution<sup>10,12</sup> containing tritiated water (1 mc./100 ml.) was perfused through the hind limbs for predetermined periods which were varied from animal to animal. The perfusion pressure employed was sufficient to maintain the preparation in an isogravimetric state, that is, one in which the total fluid space of the perfused muscles neither decreased nor increased in size. After perfusion the two gastrocnemii were rapidly and carefully removed, blotted and weighed. They were then transferred to the microdistillation apparatus shown in Fig. 1, and there distilled at 105° C *in vacuo*. The distillate was trapped by freezing with acetone-solid carbon dioxide. In the final calculation allowance was made for small losses of distillate in the vacuum line. Weighed samples of distillate were analysed on a liquid scintillation counter. By reference to analysis of a similarly distilled aliquot of diluted perfusion fluid, the tritiated water space was back-calculated. In such calculations appropriate allowance was made for the loss referred to here; model

experiments showed that any minor inaccuracies incurred in the application of this correction would have an extremely small effect on the final figures. These are shown graphically in Fig. 2. All muscles analysed were taken from rats in the weight range 229–255 g. The equilibrium figure for the water spaces of these muscles was found to be  $70.2 \pm 1.4$  per cent.

For comparison, the percentage water content of another series of gastrocnemii was determined by desiccation at 105° C for 24 h (constant weight). These results are shown in Fig. 3. Rats with a wide range of body weights were used (55–300 g); but, confining attention to muscles taken from those rats the weights of which fell in the range 229–225 g, Fig. 3 shows that these should have had a water content of approximately 75 per cent. There is thus a discrepancy of 4–5 per cent between the two sets of values.

Although it is not possible from the present data to assess the parts played by various factors in bringing about this discrepancy, we can speculate on their nature, assuming completeness of perfusion. The possibility of a tritium-hydrogen exchange, which would give rise to retention of tritium in the dried muscle debris, and

therefore to spuriously low tritiated water spaces, has already been mentioned. Penetration of tritiated water into the extracellular regions within the tendinous parts of the muscle might well be so slow that whereas the entire fluid space of the muscle might appear to have equilibrated within 20–30 min, this small but specialized region of the extracellular space might well continue to equilibrate very slowly over a very much longer period.

Water in other regions of the extracellular space might behave in the same way. The hydration shells of proteins and of mucopolysaccharides are two such possible regions, corresponding, perhaps, to Overton's "bound" water. The extracellular space would therefore be the region to which the discrepancy between the desiccation and tritiated water spaces might most plausibly be ascribed.

Thus it is possible that the apparent equilibration plateau of the space/time curve in Fig. 2 might well approach a value of about 75 per cent over a long period, that is, it might correspond to the desiccation value. This suggestion would be consistent with the view that a small volume of the extracellular water in muscle is only very slowly exchangeable. Nor is this view necessarily incompatible with the finding of previous workers<sup>13</sup> that the whole body tritiated water and desiccation water spaces correspond, as the exclusive effect of protein and mucopolysaccharide hydration shells would be very much less significant in the whole body. Should this be the case there would be valid grounds for emphasizing that the differentiation of muscle water into "readily" and "non-readily" exchangeable moieties would have quantitative as well as qualitative significance.

### Dorsal Light Receptors

THE dorsal ocelli of adult insects are present in some representatives of almost all orders except Collembola and Ephemeroptera<sup>1</sup>. Despite their wide occurrence among orders of insects, most hypotheses of their function have usually been *ad hoc* (for summaries of theories, see refs. 2–4). The physiological nature of the organs, their diversity throughout thousands of species, and their complex role in the integration of behaviour have not yet been thoroughly explored. Knowledge about these organs has begun to accumulate, and recent behavioural works on bees<sup>5,6</sup> and on wasps<sup>7</sup> give rise to the possibility that the ocelli may be associated more closely with visual perception than was previously thought. This communication is a preliminary report of the possibility that the ocelli act as visual sensitivity adjusters.

Much information has been accumulated about the ocelli, and the findings can be summarized as follows. (1) The ocelli do not form distinct images or, if they do, such images fall behind the retinal area and thus cannot

be perceived by insects<sup>2,4,8,9</sup>. (2) They react extremely rapidly to fluctuations in light<sup>10</sup>. (3) They usually occur in winged insects<sup>11</sup>. (4) Bees<sup>6</sup> and wasps<sup>7</sup> cease to forage at definite threshold intensities of light. The size of the ocelli appears to be related to the light intensity thresholds at which bees forage. Those with small ocelli are restricted to bright sunlight, while those with large ocelli (greater than 0.37 mm) can forage during day and night. (5) Blinding the ocelli decreases the visual sensitivity of bees<sup>6</sup> and of flies<sup>4</sup> during phototaxis. (6) Worker honeybees with blinded ocelli must forage at substantially higher light intensities than normal workers<sup>6</sup>.

**Function of the ocelli.** The general hypothesis of function which may fit all these behavioural and physiological findings is the following. The function of the ocelli can be thought of as analogous to that of the pupil of the human eye. Rather than being "stimulatory organs"<sup>4</sup>, they seem more likely to be moderators of the intensity of neural signals from the compound eyes, thus serving as extra-ocular adjusters of visual sensitivity. In particular, they allow a quickly flying bee or wasp to maintain its visual discrimination over a wide range of light intensity fluctuations, such as would be encountered in forests.

Light adjustment would seem to be a critical factor in visually oriented flight. Shielding pigment migrations in the compound eyes probably serve as long-term adjusters, because they are relatively slow<sup>12</sup>, while the ocelli would function centrally for quick adjustment. Hence large ocelli combined with sensitive, large compound eyes with pigment migrations would allow an insect to fly over a wide range of light intensities (both diurnal and nocturnal). Not all flying insects would need ocelli, but those without them would be limited in speed, direction and ability to continue flight under changing environmental light (for example, partly cloudy skies). A strongly diurnal flying insect (having reduced sensitivity of receptors, stationary shielding pigment, and few or no ocelli) could forage during daylight by avoiding shadows, but is unable to fly under reduced general environmental light (overcast sky). At the opposite extreme, ocelli and pigment migrations in the compound eyes may not be needed at all for a nocturnal flier which conceals itself well in the daytime and has no need to pass through strong light. For example, Johnson<sup>13</sup> has mentioned that most aphids (day fliers) will take flight if the light intensity is above 20 ft.-candles; whereas most noctuids, which are crepuscular or night fliers, will not usually take off when light is more than 20 ft.-candles in intensity. Such limits may not be vague behavioural entities, but may actually reflect restrictions on visual perception imposed by structural limitations.

The hypothesis that the ocellus serves as a sort of "pupil", that is, that it adjusts visual sensitivity, fits well with the pattern of occurrence of ocelli in bees. Bees (and, I strongly suspect, wasps) with different ocellar sizes tend to fly during different light intensities (Fig. 1). The larger the ocellus, the wider the range of light intensities under which they forage. The nocturnal bee, *Sphecodogastra texana*, has large ocelli in relation to the size of its head, and can forage not only under moonlight but also during the day. Whether the ocelli enlarge in order to maintain their function or whether their increased size enhances the ability to forage under low light remains to be determined by further testing.

**Control mechanisms.** For an indication of the necessity for quick and efficient visual adjustment mechanisms in accordance with increases in absolute speed, one needs only to look at birds. Unlike the slower mammals, including man, birds have not only photomechanical movements of receptors in the retina but also extremely fast pupillary movements often capable of great excursions<sup>14</sup>. The increase in visual sensitivity, along with their enhanced condition, is easily accepted as a prerequisite for dealing with visual perception at increased speeds. Movement necessitates good visual control not

Fig. 1. The flight range of bees with different ocellar sizes. Left to right, the dots represent the light intensity thresholds of foraging for *Chilicola ashmeadii*, *Ezomalopsis (Ezomalopsis) sp.*, *Pseudogochloropsis nigerrima*, *Apis mellifera*, *Thygater analis*, and *Sphecodogastra texana*. The range of light intensities over which each of the species forages is the vertical distance from the highest light intensity of the day to the light intensity threshold of each bee.

only over fluctuations in background environmental lighting (day-night), but also over the increased rates of change of light intensity connected with passing through shadows. The rates of visual adaptation must be proportional to the absolute rates of light intensity change connected with velocity. If the visual adjustment mechanisms fail to keep pace with changes in light intensity, momentary loss of perception occurs which may result in collision and possible death.

As in birds, one would expect to find quick visual adjustment mechanisms in flying insects. This may

indeed occur. Interestingly, Kalmus<sup>11</sup> found that the possession of ocelli was correlated with the possession of wings. Likewise, neurophysiologists<sup>3,15</sup> have been impressed by the speed with which the ocelli respond to fluctuations in light intensity. Although visual pigment migrations occur<sup>12</sup>, they are rather slow, but they could certainly account for long-term adaptation to background light on a basis similar to the photomechanical movements of receptors in bird retinæ. Rather than having quick sensitivity adjustment and visual acuity tied up in the same structure, as in the human eyeball, these functions could be carried out in insects by two separate structures, the compound eyes and the ocelli.

In the human eye during quick fluctuations in light intensity, a "steady state" of incoming signals to the striate cortex is maintained by means of the pupillary reflex. This control mechanism can be imagined as a simplified feedback system which adjusts the magnitude of incoming signals (Fig. 2a). A drop in light intensity on the retina and on the macula lutea, in particular, causes a decrease in the magnitude of signals to the optic portion of the thalamus which then stimulates the iris to open, assuring a steady state of the signals coming into the decoding centre. (For a neurophysiological description of the synapses involved see ref. 16.)

In the insect, rather than a feedback system connected with the compound eye, a parallel, non-feedback system may have evolved. The ocelli monitor change in light intensity and adjust the magnitude of incoming signals (Fig. 2b). As the light intensity drops, decreasing the magnitude of signals from the compound eye, the ocellus increases its stimulation, probably increasing the sensitivity of secondary neurones to the lowered magnitude of signals, thus maintaining a steady state of signals into the decoding centre. Some caution is, however, needed here. This may only be the mode of operation in rather moderate background light. Although Ruck<sup>17</sup> found that during

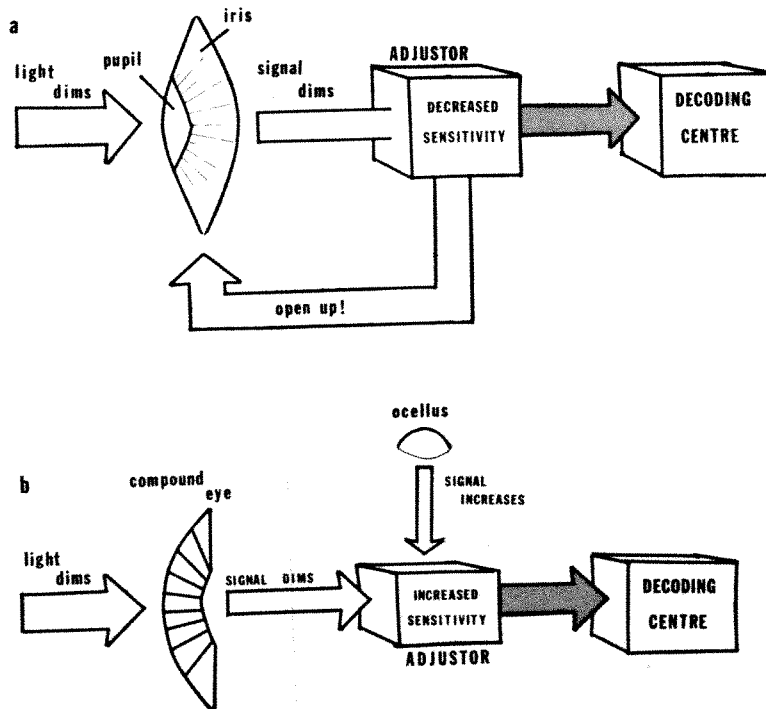

Fig. 2. a, Model of the pupillary reflex as a feedback system. Drop in light intensity decreases the magnitude of incoming signals to the optical portion of the thalamus (adjustor), increasing the signals of effector neurones to the iris. Opening the pupil increases the light intensity falling on the retina, thus maintaining a steady state of incoming signals (dark arrow) to the decoding centre. b, Model of ocellar adjustment as a simultaneous input. When the light level dims quickly, causing a decrease in the magnitude of signals coming into the optic lobe, simultaneously the ocellus reacts to the drop by increasing its signals. The ocellar stimulation presumably increases the sensitivity of neural ganglia to the lowered signals from the compound eyes, thereby maintaining a steady state of signals to the decoding centre.

moderate background light high light intensity tended to decrease or eliminate rapid spontaneous firings of the ocellar nerve stalk, very low background light also tended to create inhibition of spontaneous signals. If change of sensitivity would correspond to impulse rate, the latter finding of Ruck may explain the rise in the light intensity thresholds of honeybees with blinded ocelli<sup>5</sup>.

I thank Dr E. O. Wilson for his helpful comments and critical reading of the manuscript. This work was made possible by a graduate fellowship from the US National Science Foundation.

### Lysosomes or Boutons?

ACID phosphatase has been localized by Gomori's technique in the form of vesicular bodies (*v*; Fig. 1) and solid spherules (*s*; Fig. 1) among the mitral and the tufted cells of the olfactory lobe of the rat and bat. Such inclusions vary in number and distribution in the mitral and tufted cells (Figs. 1-6). In some cells the granules are limited in number and are seen lying on one side of the nucleus (*n*; Fig. 2). There is polarization on the side from which the processes arise. Positive filamentous bodies occur in such cells (*f*; Fig. 2). It has been established that in neurons the acid phosphatase positive granules represent the lysosomes and they originate from the Golgi apparatus<sup>1</sup>; thus it is possible that the filamentous network may represent the part of the Golgi apparatus from where the lysosomes originate as often the lysosomes extend within the processes of the mitral cells (arrows *PR*; Figs. 1 and 2). In some of the processes, however, the acid phosphatase positive lysosomes are not seen (*PR*; Fig. 3) and in such cases the lysosomes are restricted to the main bodies. Figs. 4 and 5 show stages of the distribution of the lysosomes of the tufted cells of the bat in the main bodies (*TC*; Figs. 4 and 5), as well as along the entire lengths of their processes (arrows *PR*; Figs. 4 and 5). In Fig. 4 the two processes of the tufted cells seem to meet (within circle) and the acid phosphatase bodies are evenly distributed along the entire length of the two processes. In a low power microphotograph of a mitral cell of the rat the entire process (*PR*; Fig. 6) from the point of emergence at the mitral cell (*ML*; Fig. 6) to the point of fusion with the glomerulus (*GL*; Fig. 6) is seen studded with the acid phosphatase positive granules.

What is the exact nature and the physiological role of these acid phosphatase positive bodies? A comparison of

Figs. 1-5. All the figures represent acid phosphatase reaction (Gomori's technique) in fresh frozen sections.

Fig. 1 shows the vesicular and solid acid phosphatase positive bodies in the mitral cell as well as in its processes (*PR*), the solid type at *s* and vesicular type at *v*. ( $\times 1,600$ .)

Fig. 2 shows the concentration of positive filaments (*f*) and associated lysosomes near the nucleus (*n*), and the lysosomes in the process (*PR*) at the arrows in the mitral cell of rat. ( $\times 1,500$ .)

Fig. 3 shows the absence of the lysosomes in the process (*PR*) of the mitral cell of rat. Mitral cells are loaded with lysosomes. A molecular cell (*M*) and granule cell (*GC*) are also seen. ( $\times 500$ .)

Fig. 4 shows two tufted cells (TC) of the bat with their processes (PR). Note the contact of the two processes within the circle and the lysosomes (arrows) contained in them. ( $\times 900$ .)

Fig. 5 shows two tufted cells of the bat (TC) with lysosomes (clear at arrows) distributed throughout the lengths of their processes (PR). ( $\times 800$ .)

our preparation (Fig. 1) with the photomicrograph of a freshly teased neurone stained by methylene blue by Hyden<sup>2</sup> shows exact resemblance as far as the distribution of the acid phosphatase positive bodies and the "synapses" in the neurones and the processes is concerned. The methylene positive bodies have been labelled as end feet (boutons) by Hyden<sup>2</sup> and the end feet or boutons have been considered as the synaptic sites located on the main bodies of the neurones and their processes. In this context it may be mentioned that two classes of glycolipids, namely, cerebroside and gangliosides, are present in the neurone system. It has also been suggested that the gangliosides are complexed with the proteins of the glycolipoprotein granules. The granules can be seen in neurones which have been stained by cationic (basic) dyes (such as neutral red and methylene blue) applied supravitaly or injected *intra vitam*<sup>3</sup>. It therefore seems possible that what Hyden has described as boutons after methylene blue staining may represent the glycolipoprotein granules. Further, as the glycolipoprotein granules have been proved to be homologous with the lysosomes<sup>4</sup>, the present results—which demonstrate that acid phosphatase positive lysosomes have the same appearance and topographical distribution as the boutons in Fig. 7—

add further evidence from the mitral cells that what has been regarded by Hyden as the synaptic sites may be simply the lysosomes distributed in the neurones and their processes. If such positive bodies are synaptic sites it is profitable to speculate about the role of the acid phosphatase, because recent evidence suggests that acid phosphatase is concerned with protein synthesis<sup>1,5-9</sup>. Ergastoplasm or ribosomal particles are found at the synapses<sup>9,10</sup>, and ion flux can produce changes in RNA during the passage of an impulse, resulting in the synthesis of qualitatively different protein for incorporation at the synaptic membrane (see ref. 10). Acid phosphatase may play a part in these processes. The acid phosphatase sites discussed here are thought to be lysosomes, however, and it is necessary to consider the role of these organelles at the dendritic sites.

Pappas and Purpura<sup>11</sup> have assigned an important role to the dendrites in the electrophysiological activity of brain, and Pope *et al.*<sup>14</sup> believe that certain enzymes play a significant part in the dendritic metabolism. The gangliosides (constituents of glycolipoprotein granules, that is, those of lysosomes)<sup>4</sup> have been reported to play a sig-

Fig. 6 is a low power photomicrograph which shows a mitral cell (ML) with its process (PR) positive along the entire length in the external plexiform layer (EP). Also note the positive glomerulus (GL) and the tufted cell (TC). The internal plexiform layer (IP) is also seen. ( $\times 170$ .)

Fig. 7 shows nerve cell from Deiters' nucleus. Dissected out by hand, photographed in phase contrast in isotonic sucrose solution slightly stained by methylene blue. This reveals the density of the synapses as small knobs on the surface. (Reproduced from Hyden<sup>2</sup>.)

nificant part in ion transport and other processes associated with membrane function<sup>12,13</sup>. Tewari and Bourne<sup>15</sup> have also suggested such a role of the acid phosphatase in the synapses of the cerebral cortex of rat. Thus it seems likely that the lysosomes, after originating from the Golgi apparatus in the perinuclear zone, migrate to dendrites to play their parts in ion transport and other phenomena like pinocytosis, with the acid phosphatase mediating the processes.

## RADIOBIOLOGY

### Cytotoxicity of Carbohydrates Heavily Irradiated in Solution

HEAVILY irradiated solutions of carbohydrates have been shown to influence the growth of cultures of bacteria<sup>1</sup>, and plant<sup>2</sup> and mammalian cells<sup>3</sup>, as well as producing chromosomal abnormalities in mammalian cells<sup>4</sup>. Steward *et al.*<sup>5</sup> have recently described the isolation from irradiated sucrose solution of a salt of formic acid which was characterized as sodium formate, and was shown to suppress the growth of carrot phloem explants.

In our earlier work on the effect of autoclaved and irradiated carbohydrate solutions on mammalian cells in tissue culture<sup>3,6</sup>, we concluded that the compound most likely to account for the persistent toxicity of irradiated solutions was the radiolytic product glyoxal. It was shown that the gross cytotoxicity of irradiated carbohydrate solutions was closely reproduced in our experimental system by a solution of glyoxal equivalent in concentration to the glyoxal present in the appropriate irradiated carbohydrate solution.

The presence of formaldehyde in irradiated carbohydrate solutions is known from the work of Phillips<sup>7</sup>, but it is unlikely that it is itself cytotoxic for the reasons discussed in our earlier paper<sup>3</sup>. The recent observation of Steward *et al.*<sup>5</sup> suggests that the oxidation of formaldehyde to formic acid, which might occur during irradiation or in the culture medium, results in the development of cytotoxicity. If this were so, glyoxal might similarly be converted to oxalic acid which must then be suspected as a potential cytotoxic agent. Because oxalic and formic acids are interconvertible, at least by chemical means, the gross effect of irradiated carbohydrate solutions might be accounted for by the system

This hypothesis was tested by the addition of formic and oxalic acids (as their sodium salts), glyoxal, or irradiated glucose solutions to the culture medium in which strain L mouse fibroblasts are grown. The culture

techniques have been described in detail in our earlier article<sup>3</sup>; the cells are grown attached to the glass surface of sealed bottles, collected by trypsinization, and the total growth after incubation at 37°C for 7 days counted electronically. The results are shown in Table 1, expressed as a percentage of growth in control cultures incubated simultaneously. Sodium formate exerts no cytotoxic effect, even at a concentration ten times higher than that shown by Steward *et al.*<sup>5</sup> to be present in solutions of irradiated carbohydrates. Sodium oxalate is also much less cytotoxic than glyoxal. It can be calculated that, even if all the glucose transformed during irradiation with 2.5 Mrads were to appear as oxalic acid, the amount of acid produced would still not account for the observed cytotoxicity of the irradiated glucose solution.

Table 1. GROWTH OF STRAIN L MOUSE FIBROBLASTS

Ordinary growth medium plus:	Percentage of control growth in 7 days	Ref.
Autoclaved distilled water (control)	100	3 and present experiments
1 per cent solution, dextrose, B.P., filter-sterilized	104	3
1 per cent solution, dextrose, B.P., irradiated, 2.5 Mrads	1.3	3
1 per cent solution, dextrose, B.P., irradiated, 2.5 Mrads, stored for two years	2.2	Present experiments
Glyoxal, 0.0073 mg/ml.	100	3
0.022 mg/ml.	71	3
0.073 mg/ml.	34	3
0.22 mg/ml.	1.4	3
0.73 mg/ml.	0.8	3
Sodium formate, reagent grade		
0.0017 mg/ml.	106	Present experiments
0.017 mg/ml.	102	" "
0.17 mg/ml.	109	" "
Sodium oxalate, 'AnalaR'		
0.022 mg/ml.	79	" "
0.22 mg/ml.	37	" "
2.2 mg/ml.	2.2	" "

These results indicate that the cytotoxicity of the formate salt which has been demonstrated by Steward *et al.*<sup>5</sup> is unlikely to be duplicated by the combined formic acid (which would appear as sodium formate in culture media for mammalian cells at pH 7.0-7.2) produced by radiolysis of carbohydrates in solution. This is also corroborated by the fact that labelled sodium formate is a common starting material used in the biological synthesis of a variety of compounds labelled with carbon-14. In these circumstances, oxidative processes involving the formation of formic and oxalic acids from formaldehyde and glyoxal cannot be expected to contribute to the cytotoxicity of heavily irradiated carbohydrate solutions.

Finally, the 1 per cent solution of glucose irradiated with 2.5 Mrads, which has been used in these studies, has been shown to retain its cytotoxicity for more than 2 years after irradiation.

## Dependence of the Oxygen Enhancement Ratio on Neutron Energy

THE data reported by Barendsen and Broerse<sup>1</sup> for the oxygen enhancement ratios in human cell cultures subjected to neutron radiation have prompted us to report the values which we have obtained for a completely different biological system—that of induction of somatic mutation in the staminal hair cells of a diploid clone (02) derived from a variety of *Tradescantia occidentalis*. Briefly, the irradiation induces the appearance of homozygous recessive mutant cells of a red colour which are distinguishable from the normal heterozygous blue cells. The system has been used previously to obtain relative biological effectiveness (RBE) values for negative  $\mu$  mesons (ref. 2) and 650 keV neutrons (ref. 3).

The inflorescences of the plants were irradiated with 200 keV X-rays, cobalt-60  $\gamma$ -rays and mono-energetic neutrons with energies ranging from 0.1 MeV to 14.7 MeV. Contamination of the neutron radiation with X-rays is believed to be less than 5 per cent in terms of the absorbed dose. Both before and after irradiation the plants were kept in conditions of continuous light and constant temperature in order to obtain a fully asynchronous cell population. For the irradiation the plants were sealed in an aluminium container with their inflorescences held together in a small tissue equivalent plastic box for a total of 50 min in aerobic exposures; for anoxic exposures the container was evacuated for 13 min to a pressure of about 2 mm of mercury and was then filled and flushed with nitrogen for a further 17 min before the irradiation began; the total time in the container was 65 min. The oxygen content of the emerging nitrogen was measured with a Hersch cell<sup>4</sup> and never exceeded 300 volume parts per million at the beginning of an irradiation.

For both X-rays and cobalt-60  $\gamma$ -radiation the results are well represented by curves of the type

$$M = \alpha + \beta D + \gamma D^2$$

where  $M$  is the mutation frequency and  $D$  is the fluence. For neutron irradiations the results fit curves of the type

$$M = \alpha + \beta D$$

Depending on neutron energy, the dose rates varied between 0.02 rad/min and 0.4 rad/min, while for both X-radiation and  $\gamma$ -radiation dose rates of 1.5 rad/min were used. X-ray experiments indicate that the mutation frequency is not sensitive to dose rate in the range 0.15–1.5 rad/min. Death of the cells at the low doses used has been shown to be negligible<sup>5</sup>.

Because of some uncertainty in the exact absorbed doses we are unwilling to quote RBE values at the present time, although they seem consistent with the previous determination for 650 keV neutrons<sup>3</sup>. The oxygen enhancement ratios should, however, be independent of our uncertainty about the absorbed doses. The results, together with their standard errors, are summarized in Table 1. These oxygen enhancement ratios are the ratios of the coefficients of the linear terms of the above equations obtained by least square fits to the experimental data and correspond to the ratios of the initial slopes of the dose-effect curves. In the case of the quadratic response

Fig. 1. Oxygen enhancement ratios as a function of neutron energy.  $\circ$ , Results from the induction of somatic mutations in *Tradescantia occidentalis*;  $\times$ , results from the survival of cultured cells of human origin<sup>1</sup>. ---, Hypothetical variation neglecting resonance scattering effects.

relationships given by the X-ray and  $\gamma$ -ray irradiations it may be demonstrated that for the oxygen enhancement ratio to be independent of the total dose the following relationship must hold

$$\text{oxygen enhancement ratio} = \frac{\beta_o}{\beta_N} = \left(\frac{\gamma_o}{\gamma_N}\right)^{\frac{1}{2}}$$

The suffixes  $O$  and  $N$  refer to the values obtained under aerobic and anoxic conditions, respectively. This is probably true in our case. The values for the cobalt-60 exposures are  $3.27 \pm 0.74$  for the ratio of the coefficients of the linear terms ( $\beta_o/\beta_N$ ) and  $2.38 \pm 0.71$  for the square root of the coefficients of the quadratic terms ( $\gamma_o/\gamma_N$ ); for the X-ray exposures the equivalent values are  $2.85 \pm 0.57$  and  $2.39 \pm 0.59$ , respectively. Within the standard errors these values are in agreement with the value of  $2.6 \pm 0.2$  found by Barendsen and Broerse<sup>1</sup> for 250 kVp X-rays despite the very different biological system.

It must be pointed out that the only neutron energy at which a true comparison between our results and those of Barendsen and Broerse is possible is at 14.7 MeV, when our result of  $1.51 \pm 0.06$  is in fair agreement with their result of  $1.6 \pm 0.2$ . For all other irradiations, either their energy differs markedly from ours, as with their 3 MeV value, or they used neutron radiation with a very broad energy spread while we have used substantially mono-energetic spectra. Both our data and those of Barendsen and Broerse are plotted in Fig. 1, showing the oxygen enhancement ratios at the peak intensities of the neutron spectra and giving the energy spread, where it is known, at half maximum intensity by means of the horizontal bars.

The high value for the oxygen enhancement ratio which we have found at 0.42 MeV requires some explanation. Apart from this energy, the ratios were obtained at energies chosen to avoid marked resonances in the scattering cross-sections of any of the elements from which the plant tissue is composed. In the region of 0.44 MeV, however, there is a marked resonance in the oxygen scattering cross-section. Chemical analysis (ref. 6 and unpublished results of Weiler and Strauss) has shown that the plant tissue contains about 80 per cent by weight of oxygen, so that the resonance was expected to produce a noticeable effect. The experiment demonstrates that heavy ion recoils must play an important part in the effect of neutron radiation on tissue, and that possibly range as well as linear energy transfer is a factor in the

Table 1. OXYGEN ENHANCEMENT RATIOS FOR THE INDUCTION OF SOMATIC MUTATIONS IN *Tradescantia occidentalis* BY MONO-ENERGETIC NEUTRON RADIATION, AND X-RADIATION AND  $\gamma$ -RADIATION

Radiation	Width of energy spectrum at half height	Oxygen enhancement ratio
<sup>60</sup> Co- $\gamma$ -ray	—	$3.27 \pm 0.74$
200 keV X-ray	80 keV	$2.85 \pm 0.57$
0.12 MeV neutrons	0.2 MeV	$1.131 \pm 0.066$
0.23 MeV neutrons	0.08 MeV	$1.31 \pm 0.11$
0.42 MeV neutrons	0.06 MeV	$2.11 \pm 0.18$
0.48 MeV neutrons	0.06 MeV	$1.365 \pm 0.083$
1.53 MeV neutrons	0.15 MeV	$1.695 \pm 0.077$
5.15 MeV neutrons	0.40 MeV	$2.05 \pm 0.13$
14.7 MeV neutrons	0.70 MeV	$1.514 \pm 0.063$

response. We hope to elucidate the relative importance of these factors in a quantitative way by an examination of the micro-dosimetry of our experiments.

We thank Dr D. R. Davies for the culture of the *Tradescantia occidentalis* and for comment in the preparation of this note. The experiments could not have been carried out without the help of the staff of the AERE Nuclear Physics Division's 5 MeV Van de Graaff and Cockcroft Walton accelerators.

### Increased Resistance of Mice to X-irradiation after the Injection of Bee Venom

It is known that the response of animals to whole-body X-irradiation in the lethal range can be modified by certain changes in their physiological state induced before exposure. For example, the administration of oestrogens<sup>1</sup>, bacterial endotoxin<sup>2</sup>, colchicine<sup>3</sup>, or urethane<sup>4</sup> to mice 1 day or more before lethal irradiation results in a modest but definite increase in the number of animals surviving over a period of 30 days. The mechanism(s) by which these diverse agents enhance the radiation resistance of rodents is not clear; however, it can be stated that their protective effect must be mediated by way of modes of action different from those of the "classical" chemical radioprotectors such as cysteine, cysteamine or AET<sup>5</sup>, which are only effective when administered immediately before (about 30 min) irradiation.

It seemed to us possible that because of the chemical composition and pharmacological effects of the known components of bee venom it might be of value as a radio-protective agent. It was thought that the venom might produce a degree of physiological "stress" in animals, and thereby elicit a neuroendocrine response (pituitary-adrenal stimulation)—the so-called adaptation syndrome<sup>6,7</sup>—which would increase radiation resistance<sup>7</sup>.

Bee venom is a complex mixture of enzymes, toxins, and unidentified substances. The biologically active constituents in bee venom include the enzymes phospholipases A and B (ref. 8), hyaluronidase<sup>9</sup>, and the haemolytic and neurotoxic polypeptides mellitin<sup>10</sup> and apamine<sup>11</sup>. The last two substances constitute the largest fraction by weight of bee venom.

The experimental animals used were genetically homogeneous LAF<sub>1</sub> hybrid male mice, 12–16 weeks of age, from the NRDL colony. The estimated X-ray LD<sub>50</sub> for these mice is 740 r. The mice were placed in perforated 50-ml. 'Lusteroid' centrifuge tubes, radially positioned around a circular wooden turntable and rotated at 3.5 r.p.m. directly under the X-ray tube. After a single exposure to the radiation, the mice were housed in suspended galvanized metal cages, two per cage, and they were observed over a period of 1 month. 'Purina' chow pellet feed was available *ad libitum*. The drinking water contained added 'Neomycin' (100 mg per cent) and 'Polymyxin B' (840 u/ml.).

Two bee venoms (*Apis mellifera ligustica*) were used in this study: the venom used in the first experiment was collected on August 29, 1965, in Ithaca, New York, by Dr Roger A. Morse, Cornell University. The second venom

Fig. 1. Radioprotection by bee venom injected subcutaneously into mice 1 day before X-irradiation.

used was collected on April 2, 1966, by one of us (W. H. S.) in Santa Cruz, California. No differences could be detected in the toxicity for mice of these two venoms.

One group of eleven male mice (4 months old) received 1.24 µg of bee venom (dissolved in isotonic saline)/g of body weight and a control group of nine mice received the equivalent volume of saline only. The injections were delivered intraperitoneally 24 h before exposure to an X-ray dose of 800 r. At the end of the 30 day period of observation 64 per cent of the mice that received the bee venom were alive, while only 22 per cent of the control group had survived ( $P=0.005$ ).

In the next experiment each of a group of ten mice was injected subcutaneously with 5.6 µg of bee venom/g body weight and a second group received 1.1 µg/g intraperitoneally. A third group of fourteen mice was injected intraperitoneally with the same volume (0.2 ml.) of saline only. (A preliminary toxicity trial had revealed that these doses of venom were at the threshold of the toxic, that is, lethal, dose for mice, administered by each of these injection routes.) Twenty-four hours later, all three groups were exposed together to a dose of 825 r. As can be seen in Fig. 1, all members of the control group died, while about 20 per cent of the intraperitoneally injected group and 80 per cent of the subcutaneously injected groups were alive at 30 days. ( $P<0.001$  for subcutaneously injected mice versus saline controls.)

In two additional experiments, groups of mice were injected subcutaneously with doses of bee venom (4.3 µg/g, or 5 µg/g) 1 day before they were exposed to 850 r. of X-rays. In both these groups the 30-day survival was 70 per cent, while none of the controls receiving saline survived. At these dosages, however, the venom was not effective in increasing survival when it was administered 30 min before irradiation, nor when injected immediately after the exposure of mice to 850 r. The fact that the venom provides protection when it is administered 24 h before radiation exposure places it in a different category from cysteine, AET and related compounds, which if they are to be effective must be administered just before irradiation and which are thought to exert their action at a radiation-chemical level<sup>12</sup>.

We have carried out preliminary chemical fractionation studies in an attempt to identify the radioprotective constituent(s) of bee venom. A polypeptide fraction, the largest component of which was identified as mellitin, has

been separated and isolated by means of chromatography in columns of 'Sephadex' gel. In a single experiment, mice were injected subcutaneously with this fraction (5.4 µg/g) dissolved in isotonic saline containing 0.01 normal formic acid. One day later, the mice were exposed to an X-ray dose of 850 r. Thirty days after irradiation 57 per cent of the mice so treated were still alive, while all the irradiated control mice injected with saline-formic acid had died.

At least three mechanisms may be invoked to account for the radioprotective effect of bee venom reported here for mice: (1) that it has a stressor-like action, thereby eliciting an "adaptation syndrome", assumed to increase radioresistance; (2) that it produces changes in the haemopoietic system, for example analogous to the effect of urethane<sup>4</sup> or of certain bacterial endotoxins<sup>1</sup>; (3) that it has antibacterial properties<sup>12</sup>. These mechanisms are now being investigated and further experiments are being carried out to separate, purify and identify the biologically active constituents of bee venom.

## MICROBIOLOGY

### Tetramethyldipicrylamine—a New Antibacterial Agent

Moore, Meyer and Hudson recently reported on a new analytical reagent, tetramethyldipicrylamine (3,3',5,5'-tetramethyl-2,2',4,4',6,6'-hexanitrodiphenylamine) and recommended it for further study in the analytical chemistry of the alkali metals<sup>1</sup>. A routine screening of this reagent by the National Cancer Institute, US National Institutes of Health, later showed its capacity to bring about a small but significant inhibition of tumour growth. A further check of its biological activity was then carried out, and is described here. The results indicate that this compound has antibacterial activity against Gram-positive organisms and several strains of sulphadiazine-resistant *Neisseria meningitidis*.

The sodium salt of tetramethyldipicrylamine was incorporated into trypticase soy broth and 1.5 per cent agar to give a final concentration of 10 and 50 µg/ml. medium. The following organisms were inhibited at the 10 µg/ml. concentration: *Staphylococcus aureus* (FDA-2098), *Staphylococcus epidermidis* (FDA-1200), *Streptococcus mitis*, *Streptococcus salivarius*, *Bacillus subtilis*, *Bacillus stercorophilus* (NIH-7953). The following organisms were not inhibited at 50 µg/ml. concentration: *Pseudomonas aeruginosa*, *Proteus mirabilis*, *Proteus vulgaris*, *Salmonella heidelberg*, *Serratia marcescens* (ATCC-13880), *Escherichia coli*, *Salmonella montevideo*.

Fourteen strains of *Neisseria meningitidis*, including both sulphadiazine resistant and sensitive organisms of group B and C, were tested. The assay was carried out on Mueller-Hinton agar as described by Frank, Wilcox and Finland<sup>2</sup>. The minimal inhibitory concentration ranged from 0.06 to 0.5 µg of the compound/ml. of medium.

Using the serial dilution assay method, *Bacillus subtilis* was inhibited by the compound at 1 µg/ml. and *Diplococcus pneumoniae* at 2–5 µg/ml. (Muir, R. D., personal communication).

A Gram-negative plant pathogenic bacterium *Erwinia* species and the fungi *Candida albicans* and *Fusarium* species were tested by an agar diffusion method. The compound was only slightly active against *Erwinia* species and had no activity against the fungi in this test.

No inhibition was found in tests using the nematode *Turbatrix aceti* or the protozoan *Trichomonas foetus* (Muir, R. D., personal communication).

These results show high activity *in vitro* against Gram-positive organisms and little or no activity against most Gram-negative organisms, fungi, nematodes and protozoa. It is interesting, however, to note that the compound shows high activity against the Gram-negative sulphadiazine-resistant meningococcal strains.

The compound, which is acidic and of low solubility, forms well defined salts. The sodium salt is readily soluble and was used for all our tests. The free acid showed no antibacterial activity.

We thank Dr R. D. Muir of G. D. Searle and Co. for performing some of the microbiological tests.

### Ultrastructural Localization of Coxsackie B<sub>4</sub> Virus in Mouse Myocardium

COXSACKIE viral infections are known to cause myocardial lesions in various animal species<sup>1</sup>. The identification and localization of the Coxsackie viral particles in the heart have not been adequately demonstrated because of the absence of morphological criteria which will differentiate virus particles from glycogen granules and ribosomes. This communication describes the ultrastructural localization of Coxsackie B<sub>4</sub> virus particles in the mouse heart by a ferritin antibody technique.

A randomly selected litter of 5 day old suckling mice of *HaM/ICR* strain was inoculated intraperitoneally with 0.1 ml. of fluid containing 10<sup>5</sup> TCID<sub>50</sub> Coxsackie virus B<sub>4</sub> in monkey kidney cells; this strain was originally recovered by Kibrick and Benirschke from a 10 day old infant who died of encephalohepatomyocarditis<sup>2</sup>. The mice were killed 6 days after inoculation. Multiple 0.5 mm cubic blocks of tissue were cut from the myocardial wall and fixed in 4 per cent buffered glutaraldehyde for 20 min. The tissue blocks were washed in phosphate buffered normal saline, immediately immersed in a ferritin conjugated anti-Coxsackie virus B<sub>4</sub> rabbit serum for 45 min,

Fig. 1. An electron micrograph showing (A) the distribution of the Coxsackie B<sub>1</sub> virus particles (V) along the tubules of the sarcoplasmic reticulum (SR). (B) and (C) show viral particles at higher magnification, with the binding of ferritin molecules on the viral particle surface (arrows). Unstained.

washed in the buffer, fixed in osmium tetroxide, embedded in 'Maraglas' and examined with an electron microscope.

Conjugation of ferritin to previously prepared and purified hyperimmune anti-Coxsackie virus globulin (rabbit) was performed according to the method of Singer<sup>4</sup>. The ferritin acts as an electron dense "tag" which when coupled to antibody can be used to detect specific antigen-antibody reaction sites. Uninfected mice of the same age but from a different litter were used as controls. Control tissue was treated in the same way as that of experimental mice.

Virus particles were present only at certain foci within the infected hearts. In the infected muscle fibres the virus particles were oriented around tubules of the sarcoplasmic reticulum (Fig. 1A). No virus particles could be detected in the nuclei. The particles had a higher osmophilia than the surrounding matrix. Their average diameter was about 20 mμ. The viral particles were roughly hexagonal in profile and on their surface the small electron dense particles of ferritin could be easily identified (Fig. 1B, C). A few sparsely scattered free ferritin particles with no specific localization were also observed in the myocytes. In the control tissue, no such viral particles were noticed.

The early stages of Coxsackie infection produce few cytopathic features. Indeed, as with many other viral infections, synthesis of specific viral proteins apparently occurs simultaneously with normal cell protein and nucleic acid synthesis for varying periods of time<sup>5</sup>. The cells continue to function and show few alterations despite the presence of a latent infection. After 5-7 days definite pathological features appear in some cells and irreversible damage with necrosis becomes apparent<sup>1,2</sup>. The damage is focal, however, and some muscle cells appear entirely

normal. It seems likely from other studies that many cells are initially infected and that the latent phase may exist for weeks or even years without evidence of overt cellular damage<sup>6</sup>.

The distribution of the Coxsackie particles along the tubules of the sarcoplasmic reticulum seems significant. Since the inner membrane of the sarcolemma invaginates into the cell at the level of the Z-band and is in close approximation with the cavities of the sarcoplasmic reticulum, this may represent the primary route of virus entry into the sarcomere from the extracellular space.

The distribution of virus particles in the myocardium is evident from these observations. The ferritin labelling method is therefore a useful procedure for identification of viral infections of heart and other organs by routine electron microscopy.

### Mutation towards Dextran Sulphate Resistance in Type 1 Poliovirus

THE use of type 1 poliovirus mutants resistant to dextran sulphate, as described by Takemoto and Liebhafner<sup>1</sup> and Takemoto and Kirschstein<sup>2</sup>, has proved extremely promising for genetic investigations. We have therefore carried out some additional investigations of these mutants with the view of using them in recombination experiments.

The present communication reports preliminary observations on some characteristics of the mutation towards dextran resistance and the relationship between the *ds* marker and other genetic characters either belonging to the group displaying covariation with neurovirulence or independent of the latter.

Our experiments were performed with clonal derivatives of the attenuated type 1 LSc2ab and of the neurovirulent type 2 MEF<sub>1</sub> poliovirus strains. The behaviour of the viral populations towards dextran sulphate 2,000 was tested by the plaque method with dextran sulphate incorporated in the agar overlay at a concentration of 100 μg/ml., as previously described<sup>3</sup>. In some cases, in which the inhibitor gradient method<sup>4</sup> was applied, the dextran sulphate concentration in the gradient plate ranged from 0 to 200 μg/ml. The other markers were tested according to techniques described in previous papers<sup>3,5</sup>. The hydrochloric acid salt of 2-(α-hydroxybenzyl)-benzimidazole (HBB) used in some of our experiments was synthesized and kindly supplied by V. A. Blaszek from the Institute of Medicine and Pharmacy in Tg. Mureș (Romania). The inhibitory action of HBB was assayed according to the same techniques as that for guanidine<sup>5</sup>.

When the parental L<sub>1</sub>S type 1 attenuated poliovirus was exposed to a dextran sulphate gradient, the large plaques formed by *ds*<sup>+</sup> particles were found to be scattered

\*\* Compare ref. 7.

†† Approximate indications resulting from the level at which plaques still appeared in inhibitor gradient (Grd) tests (in this case: 6 cm from the base of the plate, that is, about 200  $\mu moles/ml.$ , the gradient ranging from 0 to 400  $\mu moles/ml.$ ).

at random over the upper three-quarters of the gradient (ranging from about 50 to 200  $\mu g/ml.$ ) (Fig. 1). This distribution pattern strongly suggests that in contra-

Fig. 1. Distribution pattern of normal sized plaques formed by the L<sub>1</sub>S type 1 poliovirus strain over a dextran sulphate gradient ranging from 0 to 200  $\mu g/ml.$  The dense crowding of normal sized plaques in the lower quarter of the flask is due to the fact that almost the whole viral population is insensitive to dextran sulphate at low concentration. This is in striking contrast to the upper three-quarters of the dextran sulphate gradient (ranging from about 50 to 200  $\mu g/ml.$ ) where a few normal sized plaques, formed by *ds<sup>r</sup>* mutants, are randomly scattered among inhibited plaques.

distinction to guanidine resistant mutants, which may be divided into several classes according to the concentration of the inhibitor to which they prove resistant, *ds<sup>r</sup>* mutants do not seem to be separable into distinct categories. If this could be confirmed, it would follow that dextran sulphate resistance is acquired by single step mutation. This inference is in agreement with Bengtsson's observations<sup>6</sup>. By plating LSc2ab strain under agar overlays which contained various concentrations of dextran sulphate Bengtsson found a sharp decrease in the number of normal sized plaques between concentrations of about 3 and 10  $\mu g/ml.$ , while larger amounts of dextran sulphate did not significantly enhance the degree of inhibition. This was considered to result from the presence of about 0.1 per cent dextran sulphate resistant mutants in the viral progeny.

In our experiments the mean proportion of *ds<sup>r</sup>* mutants in the parental L<sub>1</sub>S population for eleven determinations, expressed as a value of log<sub>10</sub>, was 2.69 (± 0.39). Thus it would appear that the *ds<sup>s</sup>* → *ds<sup>r</sup>* mutation involves only a very small region of the viral genome. This assumption was supported by further experiments<sup>7</sup> in which nitrous acid was shown to induce this mutation.

The results of our experiments concerning the relationship between the *ds<sup>r</sup>* character and several other poliovirus markers (*MS*, *t*, *mp*\*, behaviour towards guanidine and HBB) are shown in Table 1. The viral populations derived from the neurovirulent MEF<sub>1</sub> type 2 poliovirus strain (*MS<sup>+</sup> t<sup>+</sup> mp<sup>+</sup>*) were resistant to dextran (Table 1, rows 1–3), regardless of the circumstances in which cloning had been performed, that is, in the presence of dextran sulphate or of another selectant inhibitor (for example, guanidine). This tallies with the initial observation of Takemoto and Liebhafner<sup>1</sup> and Takemoto and

\* *mp* equals mouse pathogenicity.

Kirschstein<sup>2</sup> on the behaviour of the neurovirulent type 1 Mahoney strain.

The attenuated type 1 L<sub>1</sub>S parental strain and some of its clonal derivatives displayed the *ds*<sup>+</sup>, *MS*<sup>-</sup> and *t*<sup>-</sup> markers (Table 1). Both spontaneous mutants and those induced by nitrous acid, which maintained their *ds*<sup>+</sup> character after several passages, performed either in the presence or absence of the inhibitor, however, retained the *MS*<sup>-</sup> and *t*<sup>-</sup> markers of the parental strain (Table 1, rows 7 and 8). A similar pattern, that is the partial independence of the *ds*<sup>+</sup> → *ds*<sup>+</sup> mutation in relation to the *crt*/40° character, was recorded by Takemoto and Kirschstein<sup>2</sup>. Moreover, it will also be recalled that Boeyé<sup>6</sup> has described the occurrence of separate mutations as well as of covariation between the *d* and *E* markers. We think that the lack of covariation between the *ds* and *d* characters on one hand, and the so-called "group of markers covarying with neurovirulence" (compare Voss *et al.*<sup>9</sup>) on the other, emphasizes the necessity for an experimental re-appraisal of the actual relationships between these markers, as well as between each of them and neurovirulence.

Our experiments on the behaviour of all these strains towards guanidine unequivocally demonstrate (Table 1, rows 1-8) that this character is not affected by selecting for the *ds*<sup>+</sup> character and vice versa, thus indicating the mutual independence of the *ds*<sup>+</sup> → *ds*<sup>+</sup> and *g*<sup>+</sup> → *g*<sup>+</sup> mutations.

Preliminary findings concerning the relationship between the behaviour towards dextran sulphate and HBB indicated the lack of covariation of these two characters. The dextran resistant derivatives of the L<sub>1</sub>S *ds*<sup>+</sup> strain displayed the same susceptibility to HBB as the parental population. Conversely, no difference was observed between the *hbb*<sup>+</sup> character in a *ds*<sup>+</sup> population after selection in the presence of HBB (Table 1, row 9) and the *hbb*<sup>+</sup> character acquired by the L<sub>1</sub>S strain exposed directly to the drug. Moreover, no change was observed in the susceptibility of the latter strain towards dextran sulphate (Table 1, row 10) after mutation from HBB sensitivity to HBB resistance.

## CYTOLOGY

### Genetic and Histochemical Studies on Mouse Spleen Black Spots

IN the course of immunological experiments involving the C57BL/Ka and C57BL/6 *Jax* strains of mice, black spots were noted on the spleens of some mice. These spots were usually found in the posterolateral aspect of the spleens, although a few cases were noted in which the spot was in the anterior portion of the spleen. Histological sections of these spots were characterized by a diffuse scattering

of pigmented cells, involving primarily the red pulp of the affected portion of the spleen. These spots occur in a number of (C57BL/Ka × Balb/C)*F*<sub>1</sub> hybrids, but not in Balb/c mice. They are present in affected strains in similar frequency from birth onwards. In order to test whether the appearance of this phenomenon is genetic, and perhaps indicative of some residual heterozygosity in our colony, we carried out laparotomies on a number of hybrid mice, then set up the following mating pairs: black spot × black spot, black spot × normal, normal by normal. The results are shown in Table 1.

Table 1. DISTRIBUTION OF BLACK SPOT OFFSPRING RESULTING FROM TEST MATINGS

Mating pair type	Black spot	Total	Percentage with black spot
Black spot × black spot	6	61	9.8
Black spot × normal	4	22	18.2
Normal × normal	12	75	16.0

The finding that two negative parents could have positive offspring rules out a dominant type of inheritance with complete penetrance. The finding that two positive parents did not have all positive offspring rules out a purely recessive type inheritance. In fact, the random distribution of positives, independent of parental "phenotype" raises some doubts about any genetic transmission of the phenomenon. We could not, however, rule out hypotheses involving the genetic transmission of a trait with variable penetrance.

The *F*<sub>2</sub> offspring were combined and assorted by skin and hair colour, and the results are shown in Table 2.

Table 2. DISTRIBUTION OF BLACK SPOT OFFSPRING IN *F*<sub>2</sub> OFFSPRING SORTED BY SKIN COLOUR

	Black spot	Total
Albino	0	40
Coloured	25	118

$$\chi^2 = 8.1, P < 0.005.$$

Thus the results demonstrate a genetic restriction on the phenomenon—the mouse must be capable of forming melanin pigment if it is to have a black spot on its spleen. The albinos were randomly distributed among the three classes of matings, and the removal of albinos from these groups did not change the proportion of black spot mice in any group.

To confirm the hypothesis that the black spot was indeed melanin, we found that the pigmented cells did not stain with Prussian blue (ruling out iron-containing pigments), did stain with DOPA oxidase, and could be bleached with hydrogen peroxide.

Because melanocytes are considered to originate from neural crest cells<sup>1</sup>, and the normal resting place of these cells is the skin (although reports of melanocytes in ovaries, thymus, and other organs have been published<sup>2</sup>), the finding of localized clusters of melanocytes in the spleen may be due to either a peculiar migration potential of these cells, a true metaplastic condition following localized prenatal trauma, or perhaps to the transport of melanin by leucocytes, as reported by Wasserman<sup>3</sup>.

I thank Miss Carlyn Vogt for technical assistance, and Mrs Olivia Sumner for carrying out the histological procedures. This work was supported by a grant from the US Public Health Service. I thank Drs W. K. Silvers, L. A. Herzenberg and H. S. Kaplan for advice and criticism in the preparation of this manuscript.

## BIOLOGY

### Electrophoretic Patterns of Larval Haemolymph-proteins in Autogenous and Anautogenous Forms of *Culex pipiens* L.

THE common house mosquito, *Culex pipiens*, has two different forms with respect to egg formation. Adult females of the so-called autogenous form can lay the first batch of eggs without taking a blood meal, whereas anautogenous females will not produce mature eggs until they have ingested blood. In spite of the many investigations of these two mosquito forms, very little is known about the physiological and biochemical basis of autogeny or anautogeny<sup>1-3</sup>. Egg formation in adult mosquitoes has been considered to depend on the nutritional reserve stored during larval development<sup>4,5</sup>; at emergence autogenous females contain more fat reserve than anautogenous females<sup>6,7</sup>. But, as Clements has pointed out<sup>8</sup>, the quantity of reserve materials cannot be the deciding factor for initiating ovarian development, because even in the anautogenous form there should be still a sufficient nutritional storage to produce a limited number of eggs. Investigation of the hormonal system revealed that the corpora allata of the autogenous females are active after emergence, whereas the anautogenous females do not secrete the gonadotrophic hormone until after they have fed on blood<sup>9-12</sup>. There is now no doubt that ovarian development in mosquitoes, as in all insects, is under hormonal control, but it is not known why the endocrine system is maintained in an active state even without feeding only in the autogenous form, while that in the anautogenous form requires a blood meal for activation.

There is no qualitative difference in the pattern of amino-acids and derivatives between autogenous and anautogenous mosquitoes<sup>13,14</sup>—paper electrophoresis showed only one protein fraction—and the total quantities of haemolymph proteins have been shown to be about the same in both forms<sup>2</sup>. We have separated the haemolymph proteins of the mosquito larvae by disc electrophoresis, which is superior to paper electrophoresis, mainly because of its high resolving power. As we report here, by means of this technique we separated more than ten fractions in the larval haemolymph and detected differences in protein patterns between autogenous and anautogenous forms.

The mosquito stocks used were *Culex pipiens* variety *molestus* (autogenous form) and *Culex pipiens* variety *fatigans* (anauto-genous form). The culturing method has been described before<sup>15,16</sup>. Larvae of both forms were grown at 25° C and fed daily with powdered dog biscuit. Haemolymph samples collected from individual larvae of desired developmental stages were centrifuged to remove haemocytes. The electrophoretic run was carried out according to the procedures used by Davis<sup>17</sup>. After separation the extruded gels were stained with amido black, destained, and preserved in 7 per cent acetic acid.

In agreement with our earlier findings<sup>2</sup> and as shown in Fig. 1, there is a rapid increase in the concentration of protein in the haemolymph during larval development. Furthermore, the protein pattern changes during larval life. In 10 and 12 day old larvae of *C.p.fatigans* there are three distinctly resolved protein bands of small mobility and large concentration; one of these remains very close to the origin (O) and has been identified as a lipoprotein. One moderately stained band moves very fast in the anodal direction and occupies a position only about 3 mm behind the tracking dye (TD). The middle part of the gel section is occupied by at least five to six faint bands which are difficult to resolve. The pattern is similar for *C.p.molestus* larvae aged 7 and 9 days except that the two bands ahead of the lipoprotein fraction have a relatively small concentration. The situation appears,

Fig. 1. Disc electrophoresis of haemolymph proteins in the larvae of *Culex pipiens* variety *fatigans* (Cf) and *C.p.* variety *molestus* (Cm). For each run 5  $\mu$ l. of haemolymph was used (120–270  $\mu$ g protein according to the stage of development). Numbers at the bottom of the electropherograms indicate larval ages in days after oviposition. O, Origin; TD, tracking dye.

however, entirely different for the fully grown larvae. In 14 day old *fatigans* larvae the gel region about 12 mm distant from the origin is occupied by five heavily stained bands, because of the increase in concentration of bands already present at earlier stages and the appearance of three new protein fractions. The concentration of the fastest migrating band also increases rapidly. The corresponding gel sections for 14 and 16 day old *molestus* larvae show likewise a much greater protein concentration compared with earlier stages, but the pattern differs from that in *C.p.fatigans*. For example, in the last electropherogram shown in Fig. 1 the first third of the distance from the origin is occupied by a single broad band. The appearance of a sharply demarcated band with a mobility of 18 mm from the origin is particularly interesting (indicated by arrow). This rather concentrated protein must be formed only towards the end of larval development, for it is absent at earlier stages. Analyses of larval tissues showed that it is present only in the haemolymph. In *fatigans* larvae of corresponding developmental ages we have found both haemolymph samples which contained no detectable amount of this protein (see Fig. 1) as well as samples which showed a moderately stained band. This variation is obviously a result of the genetic heterogeneity of the anautogenous stock.

The protein fraction already mentioned occurs regularly and is especially concentrated in the "autogenous" larvae, and so it would be interesting to know whether it is related to ovarian development in adult mosquitoes. Our preliminary examination of the protein composition in freshly laid eggs indicated that there are differences between autogenous and anautogenous forms, but no protein components with mobilities corresponding to those in the larval haemolymph could be found. This means that there is at least no direct utilization of this haemolymph protein for yolk formation. Its appearance shortly before pupation suggests that it is involved in metamorphosis. It is, of course, also possible that it is linked in a certain way to the endocrine system of adult mosquitoes.

### Low Apparent Oxygen Requirements of Deep-water Fishes in Lake Tanganyika

THE lower limit of dissolved oxygen at the south of the very deep Lake Tanganyika (maximum depth 1,470 m) is normally around 200 m. Fish have been caught at about this depth by gill-nets on the bottom, and so I decided to make use of the unusual opportunity provided to investigate *in situ* the apparent tolerances of the fishes there to low oxygen concentration.

Gill-nets were set at intervals between about 150 m depth and the anoxic level, in the two southern arms of the lake. In each setting, one or two "fleets" of nets were set at about the same depth, that is, along the bottom contour. A fleet consisted of ten nets, each net 46 m long and each a different mesh size in the range 3.8–15.2 cm (stretched mesh) in 1.3 cm increments. Water was sampled for oxygen analyses (standard Winkler analysis) 1.5 m above the bottom near each fleet, and also at several levels above the nets at the times of fishing. A mean value from two or three titrations was taken for each sample. Bottom profiles and relative positions of the nets are shown in Fig. 1a and b, together with dissolved oxygen curves. Depths of settings and oxygen values near the bottom are listed in Table 1. Fish catches are detailed in Table 2.

At the lowest depth where fish were caught (212/215 m in the south-east arm), oxygen values varied from 19.2–

7.9 per cent saturation (1.44–0.59 p.p.m.). Of five species represented there, three species were caught along the nets to their lowest limit. No fish were caught nearby in 220 m in 2.3 per cent oxygen saturation (0.17 p.p.m.). Stomach contents indicated reduction in the variety of diet towards the deeper end of the distribution ranges. Most stages of maturity were represented with no significant preponderance of any stage, or in numbers of either sex. No marked size gradients were apparent near the oxygen limit.

Other information of relevance was obtained during bottom fishing in the south-east arm in July and August 1961, when deoxygenation of much of the bottom, caused apparently by shoreward surges of anoxic hypolimnetic water, was observed on two occasions, each of which lasted at least several days<sup>1</sup>. Gill-netting was carried out at the same time as the hydrological measurements, and species of fish caught when oxygen was absent or present in small concentrations are listed in Table 3.

It is important to establish whether the fish caught at the bottom normally live there. Some of the deepest dwelling species do undertake long diurnal migrations to near-surface levels<sup>2</sup>, and much shorter movements would be sufficient to reach well-oxygenated water; according to the curves in Fig. 1a and b such movements need not exceed 50 m from the bottom. Some evidence may be adduced to show that most benthic fish remain at the bottom. (a) In hundreds of purse-seine catches examined no benthic fish other than *Lates mariae* and *L. angustifrons*, species of *Bathybates* and *Dinotoplerus cunningtoni* were found. Furthermore, few *Lates* less than 40 cm long occur in purse-seine catches, yet a large part of the *L. mariae* population on the deep bottom is less than 40 cm<sup>3</sup>. The purse-seine often fishes within 20 m of the bottom, and more of the deep benthic species should appear in catches if they undertake vertical movements even of this

order. (b) Several species appear to tolerate the temporary absence of oxygen (Table 3), which implies that they may be able to live normally in quite low concentrations (<2 p.p.m.).

In the extensive published data on minimum oxygen requirements of fishes determined in laboratory conditions at different temperatures and often with acclimated fish<sup>4-7</sup>, there are several instances where requirements are less than 1 p.p.m. On the other hand, the relatively few field observations<sup>8,9</sup> indicate that fish do not usually survive in nature where temperatures are between 15°–26° C in concentrations of less than 2.9 p.p.m. of oxygen. Discrepancies between thresholds observed in laboratory conditions and in natural habitats have been explained<sup>4</sup> in terms of the difference between survival in short-term adverse conditions, and in circumstances where feeding, growth, reproduction and competition demands must be met<sup>10,11</sup>.

The fish caught in Lake Tanganyika in concentrations of oxygen of almost 0.6 p.p.m. were presumably in an active metabolic condition. They must have been swimming actively to have become "gilled" in the net, and most stomachs not everted (because of rapid hauling to the surface) contained food. Provided that activity was sustained by respiration at the bottom, the oxygen concentrations there were remarkably low in relation to those believed to be necessary in general in natural environments elsewhere. Although some tropical Protozoa can live in anoxic freshwater<sup>12</sup>, no data concerning tropical fish are available for comparison except for *Tilapia nilotica*<sup>13</sup>. This species when forced to swim in water with 1.2 p.p.m. of oxygen at 21°–26° C survives at least 6 h.

In many fish species oxygen consumption increases sharply as temperature increases, but a relatively slow rate of consumption in tropical fish would have considerable adaptive advantages because of the inverse relationship between oxygen solubility and water temperature. If, however, rates of metabolism and energy requirements are similar in the same temperature range for tropical and temperate fish, the low oxygen tolerances cited here suggest that oxidative respiration may be supplemented by anaerobic respiration. (Work with trout<sup>14</sup> indicates that a fraction of its standard metabolism may be derived anaerobically.) Several of the common benthic fish in the south of Lake Tanganyika range from depths where oxygen concentrations should be great enough to satisfy all energy requirements to depths where concentrations are less than 1 p.p.m. and colonization of the deep bottom has perhaps been assisted by a capacity to change to anaerobic means of respiration. That this can occur without long acclimation is suggested by the survival of *Chrysichthys stappersii* and *Hemibates stenosoma* during the seasonal anoxic surges. Comparison of the haemoglobin content and tissue metabolism (in particular, the possible accumulation of lower acids or fat) of the same species taken at different depths may show that a build-up in anaerobic adaptation occurs towards the deeper end of their range.

### Function of Combs in Ectoparasites

MANY ectoparasitic insects are characterized by one or more regular rows of closely set, large stout spines. These rows of spines are termed combs, or ctenidia, and have evolved independently in fleas (Siphonaptera), bat flies (Nycteribiidae), bat bugs (Polytenidae), and in the beaver beetle *Platypsyllus*. Hitherto there has been little evidence about their function. It has recently been shown<sup>1</sup> that the spacing of spines in the combs of fleas bears a close relationship to the diameter of the hairs of the appropriate host. The gap between the tips of the spines is usually about 1.75 times greater than the average diameter of the host's hairs, but the gap narrows almost to zero towards their base. The same relationship occurs between the combs of Nycteribiids and the fur of their Chiropteran hosts. The general applicability of this principle among ectoparasites was confirmed by measuring the comb of *Platypsyllus castoris* and the fur of the beaver. The results are summarized in Fig. 1.

The precise mode of action of the combs can be understood by considering the regularity of this quantitative correspondence and by examining the behaviour of the parasite on its host. Because the free edges of the combs always tend to point posteriorly, the hairs of the host do not become trapped between the ctenidial spines during normal forward locomotion. When a flea is dragged backwards, however, its combs catch in the host's fur. This process is assisted in two ways by the host's hair structure. First, hairs are not perfectly smooth, and in many mammalian species are characterized by deep serrations and by irregularities of cross section. Irregular projections, termed nodes, are also common on the downy barbules of birds. Second, the separate strands in fur or down do not lie parallel to one another. Most mammals show a differentiation of hairs into guard and contour hairs which are long and straight, and under-fur hairs which are much more abundant, and are finer, short and often wavy. The hairs of the under-fur often cross each other repeatedly. When an ectoparasite is moved backwards therefore it is not only the irregularities on individual hairs which become trapped between the spines, but there is also a hair tangling action analogous to that which occurs when a very fine comb is drawn through untidy human hair. The resistance to backward movement can be felt distinctly by dragging a flea through the fur of its host.

Fig. 1. Relationship between the diameter of host hairs and the spacing of ctenidial spine tips. ○, *Nycteribia biarticulata*; □, *Platypsyllus castoris*; ●, fifteen species of flea<sup>1</sup>.

The survival value of the action of the combs becomes clear when we consider the situations in which ectoparasites are likely to move backwards. Fleas, at least, never do so by their own activity. Backward movement is imposed by two factors: violent movements of the host which tend to dislodge the parasite, and gripping and pulling by the host's mouth or paws. When disturbed on the host, both fleas and Nycteribiids adopt a head-down posture in the under-fur near the skin surface. It is thus their hind parts which are likely to be seized by the host. In any event, it is only backward movement which can dislodge them, and this means that the under-fur will catch in the combs. There is abundant evidence<sup>2-4</sup> that the killing of ectoparasites by the host is a major factor limiting their populations. The mechanism of the combs can therefore be regarded as an adaptation resisting dislodgement or capture by the host. It is proposed that this is the selective advantage which underlies their convergent but independent evolution in such widely differing insect groups.

### Leaf Status and Photoperiodic Control of Flower Initiation in a Late Variety of Pea

IN the absence of significant effects caused by partial defoliation in 'Greenfeast' peas, Sprent<sup>1</sup> has proposed that foliage leaves are involved in the long day flowering response of this pea variety in a qualitative rather than quantitative fashion. I agree with respect to the leaf area present at flower initiation<sup>2</sup>. I have investigated photoperiodic induction phenomena in 'Greenfeast', and suggest that the first formed foliage leaves do play an important though temporary, quantitative part in the flowering behaviour of this late variety.

I made a series of daily transfers to 8 h short days of plants germinated and grown in continuous light. The same light intensity (3,500 ft.-candles) was used for both photoperiods. Artificially lit controlled environment cabinets<sup>3</sup> allowed transfer from a cabinet giving continuous light to one giving an 8 h day without changes in light intensity or growing temperature. Fig. 1 shows that a stage of development was reached after 14 days in continuous light when the node of the first flower (NF) was predetermined and was independent of the later photoperiodic regime. Only 12 days of growth in continuous light was required for about 50 per cent of the plants to initiate the first flower at the same node as plants kept continuously in the light until flower primordia were present. This irreversible commitment to flower at a predetermined node suggests that photoperiodic induction has occurred in this quantitative long day plant. Induction was achieved at least 5 days or 3 plastochron intervals before leaf initiation at the flowering node (see N values). Also, a preliminary histochemical investigation has shown that the flower primordium initials are not formed until the subtending leaf is morphologically discernible by dissection. Thus the possibility that the commitment to flower was a result of flower primordia already present at completion of induction can be excluded.

The number of nodes bearing unfolded leaves (Fig. 1) before and at induction are particularly relevant to the role of the leaf in flowering. In general, the photoperiodic reactions involved in attainment of the induced

Fig. 1. The relationship between node of first flower (NF) and number of days in continuous light before transfer to 8 h day. Changes in leaf status for the same time scale are shown for nodes bearing unfolded leaves (NL) and total number of nodes formed (N). The former values refer to the number of nodes from the cotyledons (counted as 0) to the last unfolded leaf. Growing temperature was 20° C. Each point represents the mean of twenty to thirty plants (NF) or ten plants (NL and N). Leaf status values were unaffected by the day length and the values given are from the control kept in continuous light. Values for the standard error of the mean are too small to show graphically with the node scale used.

state were fully completed when the fifth leaf was unfolded. Growing temperatures affected this value to some extent and the leaf number at induction in several experiments at 20° C (5.3) was slightly but consistently larger than at 15° C (4.8) and 10° C (4.5).

The results of defoliation and masking experiments conducted at various times indicate that the foliage leaves at the third and fourth nodes are the most likely sites for the photoperiodic reactions concerned in induction in intact plants. The main results of one early experiment are typical (Table 1). Small but significant increases in NF values occurred only with complete removal of the third leaf (0.7 nodes) or the third and fourth leaves (1.6 nodes). The magnitude of these increases was reduced if the defoliation treatment was severe enough to cause a reduction in rate of leaf initiation. Partial defoliation at the third and fourth nodes is ineffective in similar conditions<sup>1</sup>; it seems likely that leaf area, particularly of the third leaf, is important. This has been tested by fractional defoliation treatments at different times before and after induction. Results so far obtained suggest a com-

Table 1. EFFECT OF COMPLETE DEFOLIATION AT DIFFERENT NODES ON NODE OF FIRST FLOWER AND TOTAL NUMBER OF NODES FORMED

This work was carried out at Hobart in June 1960 in a heated glasshouse in a 19 h day.

\* Leaflets and stipules removed before the leaf unfolded from the apical bud. Scale leaves at first and second nodes.

† All plants dissected 41 days after soaking. Note reduced rate of leaf initiation with removal of more than two foliage leaves.

plex relationship between critical area, node position and number, length, and light intensity of the inductive cycles. One clear result, however, was that post-induction defoliation did not affect NF values unless the rate of leaf initiation was also affected (compare Table 1). Evidently completion of photoperiodic processes in the leaf and passage of the inductive stimulus out of the leaf occurs at about the same time. Some of the hitherto puzzling features of flowering behaviour in peas and in particular the ineffectiveness of the type of defoliation treatments described by Sprent<sup>1</sup> may be explained on this basis.

### Isolation of a Sex Hormone from the Water Mould *Achlya bisexualis*

*Achlya* is a genus of filamentous aquatic fungus inhabiting fresh-water lakes and ponds. Some years ago, Raper established that sexual reproduction is initiated, in certain members of this genus, by a diffusible substance secreted into the surrounding water by the female mycelium<sup>1</sup>. This substance was named hormone A. In response to the hormone, the male hyphae produce specialized branches<sup>2</sup> and at the tips of these branches antheridia are delimited<sup>3</sup>. An attempt to isolate the hormone from culture liquids of *A. bisexualis* gave a highly active though amorphous substance<sup>4</sup>. We have continued the investigation of hormone A and have isolated from strain T5 of *A. bisexualis* a crystalline compound which at high dilution induces branching and formation of antheridia in a number of male strains of *Achlya*. An account of the isolation of this hormone, which we wish to designate "antheridiol", is given here.

Antheridiol was produced in Fernbach flasks, each containing 360 ml. of sterile medium inoculated with 10 ml. of a suspension of zoospores from *A. bisexualis* T5. The composition of the culture medium was as follows: edamin (a hydrolysate of lactalbumin), 400 mg; dextrin, 2,400 mg; calcium glycerophosphate, 30 mg; calcium carbonate, 500 mg; calcium chloride (0.5 moles/l.), magnesium sulphate (0.5 moles/l.), KCl (1 mole/l.), 1 ml. each; distilled water, 1 l. The flasks were incubated in a stationary position for 3 days at 25° C. The mycelium was removed by filtration and the pH of the culture filtrate was adjusted to 4 by adding hydrochloric acid, which at the same time dissolved the fine suspension of carbonate. A weekly batch of 240 flasks gave 85 l. of culture liquid assaying about  $3 \times 10^6$  dilution units of hormone per litre<sup>5</sup>. More than 90 per cent of the active material was removed by two extractions with 13 l. of methylene chloride. Concentration of the extract *in vacuo* on a water bath (50° C) gave 800 mg of a brown gum which had an activity of about  $3 \times 10^6$  u/mg.

The gum (3 g) was chromatographed on silica gel (300 g) with ethyl acetate as solvent. The bulk of the material had low activity and was eluted in the early fractions (the volume of each fraction was 100 ml.). Next were fractions which gave about 50 mg of a crystalline amide,  $C_{11}H_{18}O_2N_2$ , melting point 158°–161° C, with negligible activity. The fractions of high activity moved as a narrow brown band on the column. They were collected, then subjected to preparative thin-layer chromatography on silica gel H (Merck) with chloroform-methanol (10:1) as solvent. This gave a pale yellow, highly active gum in

which crystals formed gradually. They were separated by adding a mixture of methanol and ether which dissolved the adhering gum. Approximately 2 mg of antheridiol was obtained as colourless crystals, melting point 240°–250° C, with an activity of about  $5 \times 10^7$  u/mg.

Because the recovery of the hormone was low and we suspected that it was being deactivated during chromatography, we turned to a method of isolation tried earlier, namely, countercurrent distribution, using a system of four solvents: water, methanol, ethyl acetate, petroleum ether, boiling point 60°–80° C. (1 : 1 : 1.25 : 1). About 6 g of gum was put through fifty transfers (volume of each tube, 150 ml.) and the most active tubes, 14–30, were combined and subjected to a second distribution of sixty transfers (volume of each tube, 20 ml.). The contents of tubes 22–34 were concentrated *in vacuo* below 50° C to remove the upper phase, and enough methanol was then added to give a clear solution which was seeded with antheridiol and set aside overnight. About 10 mg of crystals was obtained. Recrystallization from methanol removed a brown contaminant giving colourless crystals, melting at 250°–255° C, which assayed  $1.5 \times 10^{-8}$  u/mg (mean of six assays). A concentration of  $2 \times 10^{-8}$  mg/ml. is sufficient to induce branching in our assay strain, *A. ambisexualis* E87, but for the delimitation of antheridia a concentration of  $10^{-6}$  mg/ml. is required.

The ultra-violet spectrum,  $\lambda_{\text{max}}^{\text{soln}}$  220 m $\mu$  ( $\epsilon$  17,000), and infra-red spectrum,  $\nu_{\text{max}}^{\text{car}}$  3,390, 1,742, 1,672  $\text{cm}^{-1}$ , of antheridiol indicated the presence of hydroxyl and carbonyl functions. The high resolution mass spectrum determined by Drs G. Arsenault and K. Biemann, of the Massachusetts Institute of Technology, gave the formula  $\text{C}_{20}\text{H}_{42}\text{O}_5$  ( $M^+ = 470$ ). Treatment of antheridiol with acetic anhydride and pyridine yielded a diacetate ( $M^+ = 554$ ) which showed peaks due to loss of one and two moles of acetic acid,  $m/e$  494, 434, in the mass spectrum. Catalytic hydrogenation of antheridiol afforded a crystalline tetrahydro derivative in which the carbonyl peaks had shifted to 1,770 and 1,710  $\text{cm}^{-1}$ , indicating the presence of an  $\alpha$ - $\beta$  unsaturated  $\gamma$ -lactone and an  $\alpha$ - $\beta$  unsaturated ketone.

This work was supported by grants from the US National Institutes of Health. The countercurrent method and solvent system were recommended by Dr Marjorie Anchel, to whom A. W. B. is indebted for assistance in the initial attempts at isolating the hormone.

### New Broad Spectrum Anthelmintic, Methyl 5(6)-Butyl-2-benzimidazolecarbamate

WE have found a series of anthelmintic compounds, one of the most potent of which is methyl 5(6)-butyl-2-benzimidazolecarbamate (II; SK and F 29044). Anthelmintic activity in this series of compounds was first found with thionocarbamate Ia. When a large number of compounds related to Ia were examined, it was found that 2-acylamino-benzimidazoles (Ib), 2-benzimidazolecarbamates (Ic) and 2-benzimidazolylureas (Id) also possess anthelmintic properties. In all cases, high activity was restricted to the lower members of the series in which the group R

Fig. 1. Left hand side, anthelmintic benzimidazoles I (a) ( $X = S$ ,  $R = \text{OC}_2\text{H}_5$ ); (b) ( $X = O$ ,  $R = \text{alkyl}$ ); (c) ( $X = O$ ,  $R = \text{alkoxy}$ ); (d) ( $X = O$ ,  $R = \text{alkylamino}$ ). Right hand side, anthelmintic benzimidazole II (SK and F 29044).

contained between one and three carbon atoms. The methyl carbamate derivative (Ic,  $R = \text{OCH}_3$ ), which seemed to be the most promising, was selected for further modification, and this led to the discovery of SK and F 29044 (II). Compound II is conveniently prepared by the reaction of 4-butyl-*o*-phenylene-diamine with carbomethoxycyanamide in boiling 2-propanol. It is a white crystalline solid which melts at 224°–227° C with decomposition.

In our first efficacy trials with SK and F 29044 we used mice infected with *Syphacia obvelata*, *Nematospiroides dubius* or *Ascaris suum*. In mice naturally infected with *S. obvelata*, three oral or intraperitoneal doses at 10–12 mg/kg/day resulted in more than 90 per cent reduction in worm burdens. Single oral or intraperitoneal doses were less effective. Three intraperitoneal treatments at 25 mg/kg/day or treatment with 0.05 per cent in the diet for 5 days resulted in a marked reduction (88 per cent to 100 per cent) of adult *N. dubius* in mice infected 3 weeks previously with fifty larvae. Larval stages were virtually cleared (96 per cent) in mice fed diets containing 0.1 per cent of the drug for 2 days, starting on the day of infection. Mice infected orally with 50,000 embryonated ova of *A. suum*/day for 2 days and fed SK and F 29044 prophylactically for 12 days were protected against the lethal effects of the infection.

A single dose of 15 mg/kg administered orally or intraruminally to sheep naturally or artificially infected removed 93–100 per cent of *Haemonchus*, *Ostertagia*, *Trichostrongylus* in the abomasum; and *Strongyloides*, *Cooperia*, *Trichostrongylus*, *Nematodirus*, *Oesophagostomum* and *Chabertia* in the small and large intestine. Its activity against *Trichuris* was slight. In cattle a controlled trial was completed in four groups of three animals each. The compound was administered intraruminally at 10, 20 and 40 mg/kg, and the fourth group was untreated. The activity at 20 and 40 mg/kg was excellent, with 99 per cent to 100 per cent of *Haemonchus*, *Ostertagia*, *Trichostrongylus axei*, *Strongyloides*, *Cooperia* and *Oesophagostomum* being eliminated.

Excellent therapeutic activity in swine was obtained against natural infections with mature *Ascaris suum*, *Strongyloides ransomi*, species of *Oesophagostomum* and *Trichuris suis* at a single oral dose of 30 mg/kg. SK and F 29044, as 0.05 per cent of the diet, prevented the appearance of verminous pneumonia in pigs artificially infected with embryonated ova of *A. suum*.

Chickens fed a diet containing 0.05 per cent SK and F 29044 for 24 h were cleared of *Ascaridia galli* and *Heterakis gallinae*. Divided doses of SK and F 29044, when administered orally to rhesus monkeys or dogs at 50 mg/kg/day for 2–4 days, were effective in eliminating a variety of naturally occurring gastro-intestinal nematodes.

In sheep a peak concentration in the plasma was observed 6 h after oral administration of SK and F 29044 labelled in carbon 2. The compound and its metabolites were excreted in the urine, and 19 per cent of the administered radioactivity was recovered in the first 24 h. The parent compound and two important metabolites were excreted. Tissue residues in muscle, fat, skin, liver, kidney, heart, bile and plasma were less than 0.1 p.p.m. 16 days after administration of an oral dose of 45 mg/kg labelled with carbon-14.

Oral administration of labelled SK and F 29044 to swine resulted in a peak concentration in the plasma after 6 h.

In 24 h 11 per cent of the radioactivity was detected in the urine, which consisted of the parent compound and two important metabolites. Tissue residues were less than 0.1 p.p.m. 21 days after oral administration of 50 mg/kg of the compound labelled with carbon-14.

A single oral dose of 500 mg/kg was well tolerated by sheep and swine. The oral  $LD_{50}$  for rats and mice exceeds 4 g/kg.

### Toxic Strain of *Fusarium culmorum* (W.G.Sm.) Sacc. from *Zea mays* L., associated with Sickness in Dairy Cattle

In 1928 there was an extensive North American outbreak of "scab" in barley, caused by the fungus *Gibberella zeae* (Schw.) Petch syn. *G. saubinetti* (conidial stage *Fusarium graminearum* Schw.). This was followed by the publication of a number of papers on the effect of feeding infected grain to domestic animals.

Bohstedt and Dickson<sup>1</sup> reported that ruminants showed no ill effects, but animals with simple stomachs, particularly pigs, were found to be very sensitive to "scab" infected grain. Mundkur<sup>2</sup> carried out feeding tests with hogs which demonstrated that barley containing 40 per cent scabby grain caused vomiting and slight intoxication but no diarrhoea or enteritis. Prentice *et al.*<sup>3</sup> extracted emetic material from culture filtrates of the following *Fusarium* species: *F. moniliforme* (one strain), *F. poae*, *F. culmorum* and *F. nivale*, when grown on synthetic liquid culture media. The only report of "fusariotoxiosis" in cattle seems to come from Russia, where oats infected with a very toxic strain of *F. sporotrichiella* produced poisoning symptoms when fed to yearling calves<sup>4</sup>.

The condition reported here occurred towards the end of autumn (May 1966), in south-eastern Victoria, at Berwick and Drouin, which are situated about 25 and 55 miles, respectively, from Melbourne. In both localities loss of appetite and decreased milk production were reported in dairy cattle after feeding on a crop of maize (*Zea mays* L.). At Berwick seven cows in a herd of forty-five showed loss of appetite and marked reduction in milk yield after feeding on maize; in addition some were scouring maize and two exhibited symptoms of staggering. Recovery and return to normal milk production occurred within a week of removing the cows from the maize crop.

When samples of the suspect maize crops were submitted to the Victorian Plant Research Institute for mycological examination, several species of *Fusarium* were isolated. Two were cultured from Drouin maize: *F. culmorum* (W.G.Sm.) Sacc. from the bract of a male inflorescence and *F. graminearum* Schwabe from the nodal region of the stem.

These species were also isolated from Berwick specimens of maize; *F. culmorum* was cultured from nodal stem tissue and *F. graminearum* from the bract of a cob. Also from the nodal stem tissue of Berwick maize plants the

following additional species were cultured: *F. acuminatum* Ell. and Ev., *F. moniliforme* Sheld., and an unidentified species, resembling but distinct from *F. dimerum*. All *Fusarium* species isolated were tested for dermal toxicity using the method described by Forgacs and Carll<sup>5</sup>. The fungal cultures to be tested were grown on sterilized maize grain for two weeks at 21°C and then extracted with ether in a cold Soxhlet apparatus. The dried ether extract was suspended in 2 ml. of olive oil and applied to a circular shaved patch of rabbit skin 2 in. in diameter. In each test, five applications of about 0.1 ml. of oily suspension were given during 2.5 days. The test was negative for all species except *F. culmorum*; however, isolants of this fungus from both Drouin and Berwick produced a very severe reaction. This species was tested on three rabbits. In each instance, the skin reddened on the third day, progressing in intensity and forming a typical haemorrhagic lesion, until finally death of the rabbit ensued on the fifth, sixth and seventh days, respectively.

We thank Dr C. Booth of the Commonwealth Mycological Institute, Kew, for identification of the *Fusarium* isolants.

## ANTHROPOLOGY

### Hereditary Deficiency of Pseudocholinesterase in Eskimos

HIGH susceptibility to the neuromuscular blocking action of succinylcholine is usually associated with a defective form of pseudocholinesterase in blood plasma; the abnormal enzyme is distinguished by its resistance to inhibition by dibucaine<sup>1</sup>. The gene frequency of this abnormality in Caucasians is estimated to be 0.019; 3.8 per cent of the population are heterozygous; and 1 in 2,800 individuals is sensitive to succinylcholine<sup>2</sup>.

A much rarer form of sensitivity to succinylcholine results from the absence in serum of pseudocholinesterase<sup>3</sup>. Only ten cases in seven families have been reported<sup>4</sup>. The frequency of this "silent" gene has been estimated at about 0.003 in Caucasians, and one person in about 100,000 lacks pseudocholinesterase<sup>5</sup>.

Two Eskimo children were apnoeic for 3-4 h after administration of a single dose of succinylcholine amounting to 1 mg/lb. of body weight. The children came from the same geographical area but were unrelated. When their sera were tested no pseudocholinesterase activity could be demonstrated. While testing random samples of serum to determine the reliability and reproducibility of the enzyme method, the thirteenth sample proved to be from an Eskimo who also lacked pseudocholinesterase.

A survey was then made of 708 samples of serum from hospital patients. Four unrelated persons among 354 southern Eskimos were found with pseudocholinesterase deficiency. No abnormal sera were found in 122 northern Eskimos, 141 Athabaskan Indians, fifty-eight Aleuts or thirty-three persons of other ethnic groups. None of the samples was resistant to inhibition by dibucaine, except

Fig. 1. Distribution of pseudocholinesterase concentrations in serum of 379 Eskimos. Units are μmoles of acetylcholine hydrolysed by 1 ml. of serum in 1 h at 37° C.

for one sample from an Aleut, and all showed normal inhibition by fluoride.

All six of the deficient individuals came from an area in Alaska extending from Hooper Bay to Unalakleet and centred on the lower Yukon River. Three came from near Mountain Village, and a general survey of all persons, 6 yr old or more, was made of the inhabitants of the villages of St. Mary's, Mountain Village and Pilot Station. Fifty-seven people examined were close relatives of known cases, while 322 were unrelated to them. As a result, nineteen cases of pseudocholinesterase deficiency are now known in eleven Eskimo families in Alaska. Only two of these families are related; and in only three families have all members been examined.

The distribution of concentrations of pseudocholinesterase in this investigation is shown in Fig. 1. The mean concentration of pseudocholinesterase in fourteen obligatory heterozygotes was 175 U with a standard deviation of 19 U. Assuming that all individuals with less than 175 U were heterozygotes, and that this was half the total, the gene frequency in 322 random samples was calculated to be 0.115. The calculated and observed distributions of genotypes are shown in Table 1.

Table 1. CALCULATED AND OBSERVED DISTRIBUTIONS OF GENOTYPES OF AN ESKIMO POPULATION

	322 random Eskimos		379 Eskimos	
	Calculated*	Found	Calculated†	Found
Normal homozygotes	252	252	292	295
Heterozygotes	66	66‡	81	76‡
Deficient homozygotes	4	4	6	8

\* Gene frequency was taken as 0.115.

† Gene frequency was assumed to be 0.121.

‡ Twice the number of persons found with concentrations of less than 175 U.

This gene frequency is too small, because index cases and their relatives were excluded. If they are included, the gene frequency is 0.121 in 379 persons. Calculated from the number of enzyme deficient persons only, the gene frequency was 0.111 in 322 random persons, and 0.145 in 379 individuals. The most probable value for gene frequency in this locality is thus about 0.12. About 1.5 per cent of the population can be expected to be sensitive to succinylcholine.

The method used in these investigations was adapted so that more serum could be used, and concentrations as small as 1 U of pseudocholinesterase could be measured. Eight deficient persons in five families had detectable activity (2-8 U) while nine in four families had none whatever. In one of the latter families, a father and five of his nine children were deficient in the enzyme.

The problem of the frequent occurrence of a benign, ordinarily rare polymorphism in a specific ethnic group has previously been encountered in southern Eskimos<sup>6</sup>.

The only explanation that has thus far been proposed is that any mutation that does occur may become quite common in a small population group that has been relatively isolated for many generations.

We thank J. Crispin Smith, Department of Anaesthesia, Montefiore Hospital, New York, for demonstrating pseudocholinesterase deficiency in the first two cases.

### Olduvai Hominid 10: a Multivariate Analysis

In a recent article<sup>1</sup> a hominid terminal toe phalanx was described (Olduvai Hominid 10). The bone was recovered from site FLK North (FLK N1), Upper Bed I, Olduvai Gorge, Tanzania. In that article morphological evidence was put forward to support the view that the bone belonged to an upright hominid with a plantigrade propulsive or striding gait. Further studies on the toe bone, and comparative series of toe bones, have included calculation of the  $D^2$  generalized distance coefficient of Mahalanobis and canonical variate analysis. The results entirely confirm the previous morphological assessment.

Nine functionally significant characters were selected for analysis; these included the maximum length, the length/breadth index, the mean mid-shaft thickness, the index of robusticity, the breadth of the head, the convergence angle (a measure of the relationship between the head breadth and the base breadth), the angle of deviation and the angle of axial torsion of the shaft. Measurements were taken from three populations of modern man; fifty specimens were obtained from London dissecting rooms, twelve specimens from the series of Bushmen skeletons held by the British Museum (Natural History) and thirty-seven specimens from a series of East African skeletons held by the University of Makerere, Uganda. Measurements were also taken from eleven gorilla and twelve chimpanzee toe bones.

The statistical analysis<sup>2</sup> of the data was based on the average covariance matrix, although there was some evidence of heterogeneity of variance between the groups. The Mahalanobis  $D^2$  test (Fig. 1) showed that the distances obtained between any two groups gave  $F$ -values which were significant at the 0.1 per cent level of probability, but the three groups of men were never separated by more than 8.5  $D^2$  units and the two groups of apes by more than 9.9  $D^2$  units. The human and ape groups were never less than 21.9  $D^2$  units apart, however, and on occasion were more than 36  $D^2$  units apart. Calculation of the single value of  $D^2$  for the Olduvai toe bone showed that its distance from the ape groups was about twice its distance from the human groups (Fig. 2). At the 0.1 per cent level of probability the Olduvai toe bone was different from those of the apes but not significantly different from those of the men.

Canonical analysis on the same data showed a clear separation between the human and ape groups when Variates I and II (corresponding to the two largest eigen-

values) were plotted (Fig. 3). Four variates were achieved but further plots produced no further discrimination. In the canonical diagram the circles are four standard deviations in diameter and thus should encompass 95.4 per cent of the observations in a group. Calculation and plotting of the variates for the single case of Hominid 10 showed that it fell clearly among the human groups.

In interpreting these results it would seem wise to bear in mind that any conclusions which are drawn must relate to the parameters which were selected for analysis. In this case the selected measurements were chosen on the grounds that they each reflect an aspect of the functional morphology of the terminal phalanx. A multivariate technique, by taking account of the correlations between individual parameters in each bone, can present the functional morphology of that bone as a unified concept and assign it a position in relation to others; clustering of points will produce a grouping of bones with similar functional affinities. It is

likely that these groups will represent populations of a Linnean species, but this is not inevitable because Linnean taxonomy is usually based on a wider selection of parameters than those which can be realized by examining a single bone.

From this analysis it is clear that, by anatomical and statistical examination of the terminal phalanx of the great toe, it is possible to discriminate functionally between pronograde quadrupedal apes and plantigrade bipedal men. It is particularly interesting that the same group of parameters taken from a fossil hominid toe bone, recovered from the Lower Pleistocene of East Africa, should so clearly demonstrate the functional affinity of this bone with those of plantigrade men. The palaeo-anthropological implication of this finding is that propulsive bipedalism, of the human type, was the form of gait of at least one group of early hominids evolving in East Africa at this time.

I thank Dr L. S. B. Leakey for allowing me to examine and report on this bone, Alan Walker for data from the osteological collection of the University of Makerere, Brian Newman for mathematical advice and the Institute of Computer Science, University of London, for the use of the Atlas computer.

## PSYCHOLOGY

### Centre of Gravity Movement in the Standing Human Body

THE position of the centre of gravity of the human body has been measured in a wide range of conditions, but in many cases a high degree of accuracy was not possible because of the crude nature of the equipment. Much less work has been carried out on the movement of the centre of gravity in quasi-static conditions, but similar remarks apply to the accuracy of the results. For the erect human body the swaying motion associated with long durations of standing is readily observed, but measurements of this movement are rare. Hellebrandt<sup>1</sup> recorded a series of positions of the centre of gravity to determine an average

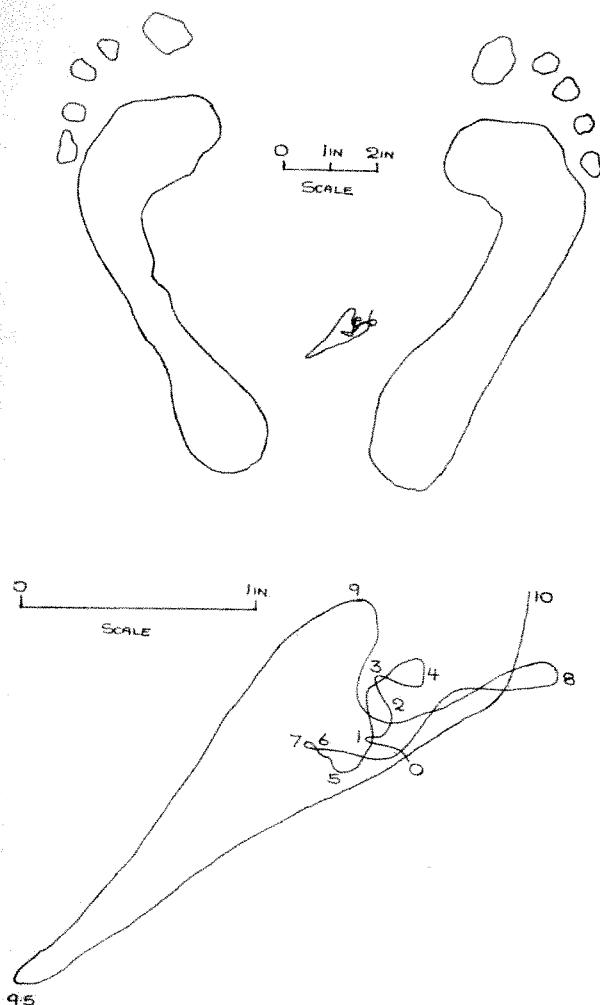

Fig. 1. (a) Base of support and path of centre of gravity. (b) Path of centre of gravity drawn to a larger scale than (a). 0-5, Eyes open; 5-10, eyes closed. This path was plotted at intervals of 0.25 sec for 10 sec.

location, while Contini *et al.*<sup>2</sup> describe apparatus by which such measurements may be made but do not seem to have produced any continuous record of the movement of the centre of gravity.

Preliminary measurements of this continuous movement of the centre of gravity have been made. The subject stands on a horizontal circular platform which is supported by three cantilevers at equally spaced positions around the periphery of the platform. Each cantilever has strain gauges attached to it, giving a continuous reading of the load on each support. Analysis of these readings allows the continuous movement of the centre of gravity of the body to be determined.

Fig. 1 shows a typical curve of the movement of the centre of gravity. The movement relative to the position of the feet is shown, together with an enlargement of the path of the centre of gravity. The numbers along the path represent the elapsed time in seconds. The figure indicates a common feature of these preliminary tests, in that each subject tends to be biased towards one foot and the movement of the centre of gravity tends to follow a line parallel to the axis of the biased foot. The greater movement of the centre of gravity with the eyes shut is as one might expect; even greater movement is found with a subject placed on the apparatus at the edge of a high flat roof, indicating a possible measurement of "dizziness".

It is proposed to develop the equipment to investigate the effect of posture and stance on stability and to provide quantitative data for the analysis of the balance mechanism

of the body; further suggestions regarding the use of the equipment would be welcomed.

## APPLIED SCIENCE

### Physical Adsorption on Porous Glass Beads

A PREVIOUS study<sup>1</sup> has indicated that a soda-lime-silica glass may be attacked by liquid water to form a porous layer on the surface. The present investigation was to show the effect of atmospheric water vapour on the surface structure of a lead glass.

Lead glass beads of 0.87-0.91 mm diameter and composition by weight 58.6 per cent silica, 24.2 per cent lead mono-oxide, 0.7 per cent barium oxide, 1.9 per cent calcium oxide, 4.5 per cent sodium oxide, 9.4 per cent potassium oxide, and 0.6 per cent alumina and ferric oxide, varied in appearance from opaque to clear. Microscopic examination of the opaque beads showed them to have rough surfaces which were characteristic of weathered glass. Atmospheric weathering processes in glass occur generally only over prolonged periods of time. The beads under investigation had never been in contact with liquid water, and therefore any deterioration of the glass could be attributed to vapour phase weathering processes. The fact that opaque beads which were given a light etch in hydrofluoric acid became clear demonstrated that the opacity was a surface property. Some of the etched beads reverted to their original appearances after treatment with water vapour at elevated temperatures, indicating that this surface effect was the result of a weathering process.

The glass beads were separated mechanically into arbitrary clear and opaque fractions. Benzene adsorption isotherms were measured at 45° C by frontal and elution gas chromatography<sup>1,2</sup> on the clear and opaque fractions and also on the original mixture of beads. All three fractions had been degassed previously under a flow of dry nitrogen for 4 h at 200° C.

Fig. 1 shows that the extent of adsorption for the various fractions of glass beads was the same. Application

Fig. 1. Adsorption of benzene on lead glass beads at 45° C. ○, Mixed beads; △, clear beads; □, opaque beads.

of the Brunauer-Emmett-Teller equation to the isotherms gave a monolayer capacity ( $N_m$ ) of  $2.35 \times 10^{-7}$  mole  $g^{-1}$  and a Brunauer-Emmett-Teller constant ( $c$ ) of 8.2. Using a cross-sectional area of  $43.7 \text{ \AA}^2$  for the adsorbed benzene molecule<sup>1</sup>, the calculated specific surface area of the beads was twenty-seven times the geometric area. The magnitude of the  $c$  value indicated that the pores were greater than  $35 \text{ \AA}$  in diameter<sup>2</sup>. Benzene adsorption on non-porous glass gave a specific surface area in agreement with the geometric area<sup>1</sup>.

If it is assumed that the extent of porosity gives a measure of the degree to which the glass had been attacked (because all the beads had been subjected to the same weathering conditions), then all the beads had been attacked to the same extent. The appearance of the beads, therefore, was not related to the extent of attack. Because all the beads had been attacked to the same extent, it was expected that the clear and opaque fractions would have the same bulk chemical compositions, and this proved to be the case. Differences in appearances of the beads were therefore probably due to variations in the surface properties of the glass.

Ross and Roberts<sup>4</sup> have shown that devitrification is a source of high specific surface areas in glass. The more opaque glass beads gave an electron diffraction pattern which was typical of saponite [ $(Mg, Al, Fe)_3 (Al, Si)_4 O_{10} (OH)_2$ ]. This crystalline material, however, was only present in trace amounts, and its state of hydroxylation indicated that it was a product of weathering. The agreement between the isotherms suggested that the opaque products of weathering (which may have been partly crystalline) did not contribute significantly to the surface areas of these porous systems.

In conclusion, atmospheric water vapour may attack glass to form a porous surface layer. The appearance of the attacked glass is not necessarily related directly to the degree of attack, but may be correlated with a discrete surface property of the glass which may initiate or inhibit the formation of opaque products of weathering. Part of the products of weathering may be crystalline.

## GENERAL

### Numerical Taxonomy and Textual Criticism of a Classical Latin Author

CRUDE forms of numerical tabulation were used as far back as the 1890s in efforts to determine genuineness or relative chronology of ancient writings, for example, by Lutoslawski<sup>1</sup> for the dialogues of Plato. The results were not without value when used in combination with other criteria, but an author's stylistic habits cannot be assumed to be constant throughout his period of literary activity, and much also turns on the investigator's subjective choice of *differentiae*.

Classification of manuscripts, an essential preliminary to any systematic textual criticism, is perhaps a more promising field for the more precise techniques now available. A manuscript tradition may be "pure bred", with successive generations of manuscripts directly copied from earlier exemplars; clerical errors and other indicative features will then be regularly distributed over the whole group of manuscripts. The interrelations of such a

monothetic (monotypic) array can be traced by routine methods and presented cladistically in the form of a family tree or *stemma*. Thus if half-a-dozen manuscripts all exhibit an identical dislocation (for example, the misplacing of the same block of lines by removal to the same place in the text), they are faithfully reproducing a feature of their common parent, and no particular problems arise.

When, however, readers or scholars in late antiquity (that is, before about A.D. 600) or in the Middle Ages (from 800 to about 1500) began to insert variant readings, either in the margins or between the lines with the desire to ease obscurities or otherwise to smooth the reader's progress, a complex situation arose. In these cases extant manuscripts show confused affiliations, which criss-cross in an apparently random fashion. Current doctrine in textual criticism treats these cases of "contaminated" or "horizontally interpolated" traditions as unamenable to systematic classification<sup>2</sup>. Editors of such texts have therefore had to fall back on considerations of idiom and style when choosing between readings in doubtful places, rather than on a critical assessment of the credentials of the manuscripts offering the variants.

This may be a premature confession of defeat, however. Inspection shows that these patterns of manuscript interrelations have the characteristics of a polythetic (polytypic) array, where *differentiae* are no longer common to the whole group under investigation. In other disciplines taxonomic methods aided by computers have enabled research workers to take such problems in their stride. In the case of Juvenal, the Latin writer of verse satire (about A.D. 100), whose manuscripts have been collated in sufficient detail for the present purpose, the number of passages which exhibit significant variants is of the order of 1,500, too few to justify investigation using a computer programme. The number of manuscripts (the operational taxonomic units in this problem) varies between fourteen and sixteen, and warrants the use of computer methods although the actual calculations are laborious.

An analogy between the behaviour of the manuscript variants and that of mutant genes suggests itself: thus manuscript variants sometimes skip one or more generations, and something akin to chiasmatic arrangement appears on occasion. Although this resemblance should not be pressed, it offers a strategy of analysis for textual criticism. Coincidence of readings in blocks of more than 300 lines in two or more manuscripts can be plotted. Each block yields not less than 40-50 points of significant variation. Thus, using similarity matrices, I was able to establish a sequence of near-neighbour relations. This is not an order of merit; it is meaningless to speak of a "best" manuscript. It is, however, helpful to further investigation to know which manuscripts can be grouped together, especially where, as in the case of the Juvenal tradition, obvious but superficial differences obscure any underlying affinities. The groupings of manuscripts for successive stretches of the satires have been tested by Spearman's rank correlation coefficient and values of the order of  $R = +0.8$  obtained, except in some instances where isolated manuscripts, which are suspect for other reasons, affect the calculation. With thirteen or fourteen degrees of freedom, such values of  $R$  yield a figure for Student's  $t$  greater than 0.1 per cent probability, that is, the odds against such consistent near-neighbour groupings being caused by mere chance are higher than a thousand to one.

Whether this taxonomic approach succeeds in penetrating to fundamental "genetic" affinities of the extant manuscripts of Juvenal is now open to debate, but I hope shortly to publish the data and reasoning in full.

## BOOK REVIEWS

### ORIGIN OF THE ROYAL SOCIETY

#### The Royal Society

Concept and Creation. By Margery Purver. With an introduction by H. R. Trevor-Roper. Pp. xvii+246+12 plates. (London: Routledge and Kegan Paul, Ltd., 1967.) 35s. net.

It seems strange that there should be so much obscurity about the origin of the Royal Society, and that there should be so much difference of opinion among historians who have written on the subject.

On one point, however, there seems to have been general agreement—that the movement which led to the foundation of this new scientific society drew its inspiration from the writings of Francis Bacon; and yet that this should be so is no less strange: Francis Bacon, Lord Verulam, statesman and philosopher, was no experimental scientist. Strongly as he advocated a departure from the teaching of the medieval schoolmen, based as it was on the works of Aristotle, and the cultivation of a new scientific approach to the problems of nature, his ideas of the methods by which this should be achieved were widely different from those of the actual founders of the Royal Society, and indeed of its fellows for the past three centuries. His conception, it might be said, was of an organized attack on the problems of science, not of experimentation by individuals and deduction from their discoveries. It is doubtful if he had any belief in the idea of individual experimental research.

It is more probable that the true origin of the Royal Society is to be sought in the character and ideas of the men constituting the group or groups which met in Oxford and London in the first half of the seventeenth century, in the years following the Civil War and immediately before the restoration of King Charles II.

It is this period and this enquiry which is the subject of Miss Purver's book. Her endeavour has been to clear up some of the obscurities and to indicate, more clearly than has been done hitherto, which of the groups of learned men, among several competitors for the honour, were the true founders of the Royal Society. It should be said at once that, although there is still room for difference of opinion on certain points, she has been highly successful in her research and her book is most illuminating.

The first historian of the Royal Society was Thomas Sprat, whose book appeared in 1667, only five years after the society received its Royal Charter. Sprat was in no doubt that the Royal Society originated in the meetings at Oxford of the group which centred around the personality of John Wilkins, the Warden of Wadham College. Later writers have tended to disregard Sprat, thinking that his view of the happenings was personal to himself, and it is one of the most valuable features of Miss Purver's book that she is able to show conclusively that his history was authorized and approved by the council of the young society.

The "experimental science club" at Oxford included among others, and besides John Wilkins, Seth Ward, Robert Boyle, John Wallis, William Petty and Christopher Wren. They met for about ten years, from 1648 to 1658. At the end of that period the members dispersed, for various reasons, the greater number going to London. There the meetings were continued, at Gresham College

and elsewhere, and the group was joined by others sympathetic to their ideas, among them Lord Brouncker, John Evelyn and Dr George Ent.

Other meetings of a similar or a comparable character had been held in London as early as 1645. Dr John Wallis, writing in 1678, and disregarding Sprat's version, considered these to have been the origin of the Royal Society. There was certainly some overlapping, for some of the members at these earlier London meetings appeared afterwards at the Oxford club. Wallis gave an interesting list of subjects discussed at his meetings, including the work of William Harvey on the circulation of the blood. Another notable figure at these earlier London meetings was Theodore Haak, a German who had settled in Great Britain, and to him Wallis was inclined to attribute the origin of this London club and therefore of the Royal Society.

Miss Purver has also investigated the activities of Samuel Hartlib and his collaborators, Comenius and others, with their ideas, put forward about 1646, of a "Universal College" in England. With these Robert Boyle and his "Invisible College" were involved, and all these early discussions and proposals clearly have their bearing on the origins of the Royal Society.

Much of the confusion, the conflict of evidence, which surrounds these activities is undoubtedly due to the period in which they occurred, for the times were out of joint. The Civil War had ended in 1646. King Charles II was recalled from exile in 1660. The intervening period was one of divided loyalties, and men would have been cautious in expressing their opinions and speaking of their associates. A little later, in 1665, when Sprat was writing his history, there was the disturbance caused by the plague and the fire of London.

There is the remarkable case, for example, of John Wilkins, whose position and influence were such that he might well have been the first president of the new society, and he would have seemed the obvious person to solicit the favour of the King and the grant of a Royal Charter. But Wilkins was married to Cromwell's sister; and the choice of a person to carry this responsibility fell on Sir Robert Moray, a Royalist who had been in exile with the King in Holland. The charter was obtained and the Royal Society was established with Lord Brouncker as its first president.

T. MARTIN

### ASTRONOMY'S HEROIC AGE

#### Quasars

Their Importance in Astronomy and Physics. By F. D. Kahn and H. P. Palmer. Pp. 112. (Manchester: Manchester University Press, 1967.) 30s. net.

THE race to publish the first book on quasars has been won by Professor Kahn and Dr Palmer of the University of Manchester. Their book is addressed to the general reader, and so the three questions we should ask first are, in descending order of importance, is it intelligible, is it accurate, and is it unbiased? The quasars have such astonishing properties, and our knowledge of them is developing so rapidly, that it is hard to be any of these things. The book is certainly accurate, as we should expect from the authors, who are distinguished for their work in theoretical astrophysics and observational radio astronomy—a happy combination. It is also reasonably unbiased, which in view of the controversies now raging is a remarkable achievement. I was, however, surprised to find that the marks they allot to the various theories of the origin of quasars add up to exactly 100 per cent. In view of the calculated sobriety with which they write about these astonishing objects, it seems inconsistent of them to be sure that the correct explanation has already been given!

The book is lucidly written, so that any difficulties it may present would come from the ideas described and not from their expression. The early chapters which are devoted to the discovery of quasars and their main observational properties are fairly straightforward, and should be understood by the general reader with scientific and astronomical interests for whom the book, according to the blurb, has been written. The theoretical chapters discussing the physical basis of current interpretations are inevitably more difficult. A brief account is given of radiation processes, the acceleration of fast particles, magnetohydrodynamics, relativity and cosmology. This is a formidable list, but I believe that the general reader will glean from this part of the book the type of idea which each of these subjects is called on to provide.

Separate mention should be made of the chapter entitled "Stars", which is the most difficult but most rewarding in the book. It deals with the stability of large masses in the manner made famous by Eddington, that is, by using simple physical considerations to derive their main properties. I would like to direct attention especially to the extension of Eddington's method to the case when general relativistic effects are important. Chandrasekhar has found by some difficult analysis exactly how the stability criterion is altered by these effects. Here a relatively simple analysis is used to obtain a reasonable approximation to this new criterion. This section will be read with gratitude not only by the general reader but also by astronomers who are not experts in relativity. I think Eddington would have enjoyed this extension of his method, although perhaps he would have added whimsically that the authors give a rather low mark (10 per cent) to this relativistic instability as the possible origin of quasars.

One day we will understand the origin of quasars, and then this book will have to be rewritten. Even now, however, we can claim that we are living in the heroic age of astronomy (and it is no disrespect to the great astronomers of the past to recognize this). The reader who masters a fair fraction of Kahn and Palmer can share in the excitement of this age, and will be prepared to understand in good part the great discoveries that are still to come.

D. W. SCIAMA

## OPTIMAL CONTROL

### Optimization of Stochastic Systems

Topics in Discrete-Time Systems. By Masanao Aoki. (A Series of Monographs and Text-books in Mathematics in Science and Engineering, Vol. 32.) Pp. xv + 354. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 116s.

This is the thirty-second text in an excellent series of books on mathematics with practical application which is being edited by R. Bellman. The present author, M. Aoki, is an eminent research worker in the field of control system optimization and fifteen of his 143 references are to important publications of his own.

As indicated by the word "stochastic" in the title, the problem of optimization is studied for cases in which the system is subject to randomly varying inputs. These inputs can be either additive, as with noise or random signals to be followed, or multiplicative, as when gains and time constants vary randomly. The whole study is performed using discrete-time so that systems are always described by difference equations. Thus the development of statistical methods is more straightforward than with a continuous-time study which may be ultimately necessary in many cases. The resulting unified treatment, however, is a commendable feature of the book.

Much of the book is concerned with the derivation of what the author calls "optimal Bayesian control". This involves the manipulation by the chain and Bayes's rules

of conditional probability densities which are used in recurrence relations for expected future cost. Then the process of deriving optimal control corresponds to the method of dynamic programming. The optimal control policies are applied firstly when noise and plant parameters are known constants, then when some of the parameters are unknown but assumed constant, and finally when such parameters are themselves stochastic.

A chapter is devoted to the problem of how to operate on noisy measurements in order to make the best estimate of the quantities being measured. Three methods are studied: least-squares, maximum likelihood and optimal Bayesian estimation, and their inter-relation is examined. The Kalman filter is derived as an example of the latter method.

The convergence of Bayesian optimization is considered together with Kalman's concept of controllability and observability applied to stochastic systems. The question of the stability of systems is also studied using stochastic Lyapunov functions. There is a long chapter concerned with approximations which may be made to simplify the formulation and implementation of optimal control policies. More work may be needed in this direction before the methods are applied in practice. The certainty equivalence principle, pseudoinverse matrices and sufficient statistics and martingales are interesting features which enter naturally into the work and are given some explanation.

The basic requirement of the reader is a working knowledge of matrices, vector spaces and conditional probabilities. Throughout the book, the author tries to be gentle to the uninitiated by the use of illustrative examples given in ascending order of difficulty. Although no exercises are set for the reader, it will form a good textbook for students of advanced control theory and it will be an extremely valuable reference book for researchers and teachers of control of stochastic systems.

A. P. ROBERTS

## THIS IS TRIBOLOGY

### Lubrication and Lubricants

Edited by Eric R. Braithwaite. Pp. xiv + 568 + 191 illustrations and 46 tables. (London, Amsterdam and New York: Elsevier Publishing Company Ltd., 1967.) 170s.

PRESENTATION of a subject which has its origin in traditional practice but wherein modern development has occurred in a number of scientific disciplines poses many problems. Not least of these is the probability that the reader may be expert in one facet while having only a superficial knowledge of the remainder. Thus, as in this book, which deals with chemistry, metallurgy and several aspects of engineering, matter which is descriptive of present or past practice must be blended with rigorous treatment of current scientific contributions. Collaborators in this volume have overcome these difficulties quite skilfully, presenting good reviews of current research in each field against a background of historical or other introductory matter sufficient to facilitate a multi-disciplinary approach. Perhaps, because the planning of the volume anticipated the Jost Report, the word tribology is not used although the volume is itself a good example of the multi-disciplinary approach denoted by this term.

In an introductory survey, Rowe departs from the conventional concern with the contact of asperities and introduces the subject of boundary lubrication by analogy with the lubrication by a soft solid of flat metal plates loaded in compression. The resistance to lateral sliding is proportional to the yield strength in shear of the soft solid, and the maximum compressive stress which can be withstood by the metal plates is, of course, their yield strength in compression. The yield strength in shear is related to yield strength in compression by a ratio of 1/2,

therefore coefficient of friction = yield strength of soft solid /  $2 \times$  yield strength of plate material. Evidence is provided from measurements of friction in forging titanium with copper or aluminium used as a lubricant which reveals close qualitative agreement with the above prediction. Reviewing recent developments of frictional theory, Rowe concludes that "welding" is not an essential feature of boundary friction but that most of the energy can be dissipated in shearing the lubricant itself. The theory of hydrodynamic lubrication is introduced in general terms without making excessive demands on the mathematical skill of the reader and without the detailed treatment which characterizes most texts on the subject. Greater emphasis is given to a descriptive treatment of the causes and prevention of wear.

Peace summarizes recent work on solid lubricants. Additives for lubricating oils present a confusing array of chemical types which must provide commercial solutions to special problems posed by engines or other machinery requiring lubrication. The final product cannot, however, be characterized in chemical terms alone and Molyneux describes some of the basic chemical formulations available, but he is mainly concerned with functional tests as prescribed in the various specifications. Although the text is quite correct some difficulty appears in connexion with the captions of some of the illustrations. Thus, Fig. 3/4*b* illustrates "ridging" failure rather than "rippling" and these are stated to occur in high-speed, low-torque conditions rather than the low-torque, high-speed conditions. The quality of reproduction of Fig. 3/4*a* is insufficiently good to determine whether or not it illustrates "scuffing" as claimed in the caption. This type of failure is characteristic of the high-speed, low-torque condition as correctly stated in the text and not the high-torque, low-speed case referred to in the caption.

The increasing use of gas turbine engines in aircraft has produced demand for improved performance of lubricating oil which can no longer be met by natural lubricants and which can only be met by synthetic fluids, notably the diester types. Goddard reviews the chemical nature and performance characteristics of synthetic lubricants generally.

For less exacting duties lubricating greases are used, and Harris shows that these are no longer based on tradition but have been the subject of much scientific study. Electron micrographs of the structures of several types of grease reveal the important part played by the network of soap fibrils or the fine structure built up from mineral based solid phases.

In a review of lubrication in metal cutting Rowe introduces the theory of Ernst and Merchant which relates the coefficient of friction at the tool face with the rake angle. This theory envisages that all the shearing takes place on a single plane of negligible thickness. To accommodate a finite relative displacement, however small, an infinite shear strain would be required which could only be associated with complete rupture. A micro-section of the cutting zone in beryllium copper suggests that shear occurred successively on a number of planes but, in the general case of a continuous chip, rupture is excluded. The authors rectify this concept by introducing what they call the "minimum energy" theory of machining. Although shearing of metal would be initiated on one plane, the material in its vicinity would become strain hardened so that subsequent shearing would take place on an adjacent plane. This leads to the prediction of a wedge-shaped shearing area, which is confirmed by photomicrographs of sections of machined areas of annealed mild steel. We are thus concerned with shearing zones rather than the shear planes postulated by Ernst and Merchant. Recent work<sup>1</sup> shows that the formation of a continuous chip is the result of plastic deformation in two zones, one embracing the shear plane of Ernst and Merchant and the other adjacent to the face of the tool. These are shown to be attributable to the variation of

strength with shear rate and the postulation of strain-hardening may be unnecessary.

Many books on lubrication concentrate on the hydrodynamics or chemistry of the lubricant to the exclusion of the nature and contribution of the surfaces being lubricated. This book avoids this criticism, for fully illustrated chapters by Morris and Pratt deal with metallic and plastic based bearings respectively.

During the discussion of any lecture on lubrication some member of the audience invariably asks, "What do I do about my car?" Such questions are answered by Greene, who deals fully with lubricants for reciprocating engines, gas turbines, rotary engines and gears. No doubt for the enlightenment of non-engineers, diagrams are provided illustrating the common types of rolling bearing. Unfortunately the captions have been transposed and a ball thrust bearing is described as a double row angular contact bearing. The illustration of the latter type is captioned as a self aligning bearing. The self aligning ball bearing is described as a roller bearing and the roller bearing is described as a ball thrust bearing. A final chapter by Cockcroft on lubrication in metal working adequately describes a wide range of processes.

Notwithstanding minor blemishes, this book is probably unique in the range of information included and will serve equally well as an introduction for the newcomer into the field or as a work of reference for the established practitioner.

## X-RAYS FOR METALLURGISTS

### A Handbook of Lattice Spacings and Structures of Metals and Alloys

Vol. 2. By W. B. Pearson. (International Series of Monographs in Metal Physics and Physical Metallurgy, Vol. 8.) Pp. viii + 1,446. (Oxford, London and New York: Pergamon Press, Ltd., 1967.) 500s. net.

THE second volume of this important reference book follows closely the pattern of its well known predecessor published in 1958. The tabulated data assembled in the first volume are brought up to date, and the enormous literature in the intervening years (1955-1964) is reviewed. This volume is substantially larger than the first, but the overall presentation, limited to six chapters, is more concise.

A new classification of the known structure types of metals and alloys is introduced in the first chapter, based not on the usual Strukturbericht symbols but on a new notation employing two characters to represent each of the fourteen Bravais lattices. This new notation will present no problem to the reader, but its adoption here will no doubt cause debate.

The bulk of the book can be divided broadly into two sections. The first of these, three chapters and 400 pages, takes the form of a vast table, compiled in alphabetical order, which summarizes the structural data and lattice parameters of many thousands of compositions of intermediate phases, metallic borides, carbides, hydrides, nitrides and binary oxides—a truly monumental compilation of most useful data. It must be noted, however, that should the references corresponding to the tabulated data be required, they lie partly in the review sections of the first volume.

The second and larger section of the book (the fifth and sixth chapters) is devoted to a meticulous critical review of X-ray structure data published between the writing of the first and second volumes. The accounts of earlier work in the corresponding chapters of the first volume are not repeated in this section, but are widely referred to, so that in this respect the two volumes are complementary. The coverage is very wide indeed and the condensed results,

detailed and amply illustrated, are presented in a most accessible and useful form.

It is difficult to find fault with this book; it would be unreasonable to do so on the narrow basis of a few omissions and inadvertent misrepresentations. It is a pleasure, therefore, to say that the second volume lives up to the standard of its predecessor to constitute a magnificent reference work on X-ray structure data, which will be greatly valued by research metallurgists and physicists.

I. WILLIAMS

## EASTERN RADIATION CHEMISTRY

### Proceedings of the Second Tihany Symposium on Radiation Chemistry

Edited by J. Dobo and P. Hedvig. Pp. xvi + 813. (Budapest: Akademiai Kiado, Publishing House of the Hungarian Academy of Sciences, 1967.) 200s.

To those who had the pleasure of participating in the first Tihany Conference on Radiation Chemistry in 1962, the announcement of a second conference promised a further useful interchange of the latest information from a wide range of sources. Subsequent reports show that this promise was more than fulfilled and this is confirmed by the many excellent contributions reported in this volume. As may be expected, east European countries were strongly represented, and the meeting presented an excellent opportunity of reviewing the present status of research which, because of language difficulties, cannot always be readily followed from published literature.

The proceedings are divided into four main parts: general (eight papers), aqueous solutions (eighteen papers), organic compounds (thirty papers), polymers (forty-two papers). This division, however, does not reveal the wide scope of the papers. These include several papers concerned with radiation mechanisms and with radiobiology, some valuable contributions on the radiation chemistry of water and related problems and a range of papers dealing with intermediates in simple organic compounds, using recently developed techniques. An unusual feature is the large number of contributions concerned with various aspects of polymer research: polymerization, graft and block polymers, solid state reactions, crosslinking and thermoluminescence. One of the most useful features is that many of the articles are commendably short, summarize the conclusions reached as a result of a comprehensive research programme and give references to the original papers in which fuller details can be found. Thus, a selection of important papers not yet available in English can be made easily. This approach is to be highly recommended; only too often papers presented at conferences are too detailed and present one aspect of a lengthy programme, with which the author but not the audience is familiar; such results are more appropriately published in the usual scientific journals.

One feature of these conferences is the opportunity it offers for informal discussions in very pleasant conditions on work in progress. I have a vivid recollection after the first conference of trying to follow an informal scientific discussion in a Budapest restaurant, while a violinist of the nationalized Zigeuner Orchestra played highly romantic music at a range of six inches alternately from left and right ear. For radiation chemists who have participated in this meeting and enjoyed excellent Hungarian hospitality, and for those who have not had that opportunity, this volume is most highly recommended as a source book. On the present showing we may expect future Tihany conferences to become an important feature in the calendar of international conferences on radiation chemistry, and their published proceedings a valuable collection of up to date short review articles.

A. CHARLESBY

## CENTURY OF STUDY

### Mongolism

Edited by G. E. W. Wolstenholme and Ruth Porter. (Ciba Foundation Study Group, No. 25.) Pp. ix + 99. (London: J. and A. Churchill, Ltd., 1967.) 18s.

In 1866 Dr John Langdon Haydon Down published a paper "Observations on an Ethnic Classification of Idiots", in the London Hospital reports, in which he drew attention to the group of children now classed as showing the features of mongolism or Down's anomaly. Any suggestion implied in Down's paper of an ethnic link between these children and the members of the Mongolian race has long since been refuted, but the term mongolism remains in use despite attempts to supplant it by Down's anomaly. The centenary of Down's paper was commemorated by the meeting of a study group at the Ciba Foundation in London on May 10, 1966, under the chairmanship of the late Lord Brain.

In numerical terms mongolism is important within the context of the more general problem of congenital abnormality. Children with this syndrome are born with a frequency of about 1 in 800 of all live births, and apart from the characteristic physical stigmata they eventually show a severe degree of mental sub-normality. Mongols form an important component of the children in any hospital for the mentally sub-normal, and mongolism is possibly the example of gross congenital abnormality with which the general public is most familiar, a familiarity enhanced in recent years through the medium of television.

Seven papers were given at the Ciba meeting and six of these had roots in various advances already made in our understanding of mongolism. Dr E. Matsunaga discussed Japanese data on parental age and birth order in mongolism, while Drs H. Forssman and H. O. Akesson discussed Swedish work on consanguinity and mongolism. Both Professor L. S. Penrose and Dr G. F. Smith, of the Kennedy-Galton Centre at Harperbury Hospital, gave papers on dermatoglyphics, while Dr Ursula Mittwoch of the Galton Laboratory dealt with the DNA content of mongol and normal cells as measured by a microdensitometer on Feulgen-stained fibroblasts. Dr M. Fraccaro and collaborators from Pavia and Stockholm discussed their data on the timing of DNA replication in *G* group autosomes in cultures of lymphocytes from mongols.

The past thirty to forty years have seen important advances in our knowledge of mongolism, and the highlights have been an appreciation of the significance of maternal age in relation to the risk of conceiving a mongol, the specificity of the dermatoglyphic findings, and the understanding that mongolism may be the phenotypic expression of trisomy of one of the *G* group autosomes, conventionally regarded as No. 21 in the Denver classification. A further important advance has been the linking of familial mongolism with the transmission of a translocation chromosome of the *D/D* or *G/G* centric fusion type, while a perplexing piece of information is the markedly increased risk of the development of leukaemia incurred by mongol children. It is perhaps a pity that on the centenary of Dr Down's paper there was no review of the advances that had been made and of the hopes for the future. In the study of mongolism we seem to have come up to one of those barriers to the acquisition of knowledge, the successful negotiation of which opens up wide and new fields of understanding. Much of the burden of future concern in research into mongolism must surely be towards knowledge of the mechanisms linking gene action and phenotypic expression. The last paper of the Ciba meeting, by Dr W. J. Mellman and collaborators from Pennsylvania, begins to deal with just such questions and is concerned with whether increased enzyme activities observed in the polymorphonuclear leucocytes of mongols can be accounted for by the localization of

specific gene determinants to chromosome 21. Perhaps the nature of gene action and phenotypic expression in mongolism will be understood long before the bicentenary of Dr Down's paper comes round.

W. M. COURT BROWN

## HUMAN INHERITANCE

### Genetics of Man

By Paul Amos Moody. Pp. viii + 444. (New York: W. W. Norton and Company, Inc., 1967.) \$7.50.

THIS book is an introduction to the principles of genetics and to inheritance in man. Based on a course of elementary lectures, it is suitable for medical students and those who want to know more about man. Each chapter has retained the characteristics of a lecture, offering problems for further study and a list of references to original works. The book remains a collection of lectures, and the references are not collected at the back and the names of the authors do not occur in the index.

The introduction to theories of inheritance is more successful than the outline of human cytogenetics. It is doubtful whether a reader would gain an adequate knowledge of the structure and behaviour of chromosomes to appreciate the applied science that is referred to as genetic engineering. He should find, however, the gradual introduction to theories of probability and methods of calculating inheritance an excellent groundwork for the study of human pedigrees.

A prospective reader need not be put off by the figures and formulae he may see as he turns the pages, for Professor Moody has succeeded in his aim of avoiding the intricacies of mathematics.

There is a simple but adequate exposition of twin studies. This leads to well balanced appreciations of the inheritance of intelligence, natural selection in human populations, the genetics of race and, finally, to a chapter on genetic counselling. Genetic counselling is becoming the fashion and those who think it has reached an advanced stage might read the last chapter for a straightforward factual explanation of its difficulties and limitations.

WILMA GEORGE

## OUR ABNORMAL CHROMOSOMES

### Human Population Cytogenetics

By W. M. Court Brown. (North-Holland Research Monographs: Frontiers of Biology, Vol. 5.) Pp. xii + 107 (31 tables, 25 plates). (Amsterdam: North-Holland Publishing Company, 1967.) 40s.

DR W. M. COURT BROWN and his colleagues at the Medical Research Council Clinical Effects of Radiation Unit have played a unique part in the history of human cytogenetics. Dr Court Brown was active in the subject from the start of its recent efflorescence (1956), and the unit which he heads is now the largest one for the mass study of human chromosomes in the world. Moreover, the geographical position of the unit is such that it is able to survey, if it wishes, the whole population in the sea-limited Edinburgh-Glasgow axis. It not only has a comprehensive filing system for all karyotypes studied, but also a team of social workers trained to follow up any case in which the subsequent history, or familial studies, are likely to be of interest. For these reasons the unit has been able to collect a unique mass of information on the incidence of chromosomal variations and abnormalities in a large population.

This book gathers together in one volume several topics on which reports have hitherto been scattered in various journals. It does not claim to be comprehensive; rather it reflects the problems which have been of particu-

lar interest to the author and his colleagues in the past few years. The topics fall under three main headings: the incidence of clearly visible abnormalities (and variants) in the mitotic chromosomes in a normal population; the problem of the chromatin-positive male; and the role and nature of the Y chromosome.

The findings are such as might be expected from a large-scale study of those morphological peculiarities of chromosomes which can clearly be seen with the aid of the microscope. The incidence of the various anomalies found is clearly listed, and the clinical manifestations of the resultant phenotypes are defined briefly; it is also shown how chromosomal alterations may be inherited in families.

In the first chapter the increase of aneuploidy with age is clearly dealt with; then the author considers the controversial subject of chromatid aberrations (these are so dependent on cultural conditions that he can only say that the whole status of chromatid abnormalities in preparations from population surveys remains to be evaluated). The conclusions about chromosome aberrations and their relation to environmental chromosome damaging agents are not much more definite, although the extensive work (of Buckton and others) on the long-term effects of radiation on the behaviour of lymphocytes has given us much basic information about the consequences of chromosomal damage. Finally, in this chapter, the author considers inherited variants in autosomes found in phenotypically normal individuals; these are found especially in the acrocentric chromosomes of groups D and G and in pair 16. It is surprising that no specific mention is made of the chromosomal satellites, for these exhibit morphological variations and it has been shown that abnormally long ones can on occasion be inherited. Perhaps the subject has been generally disregarded because of early erroneous ideas of others on the use of the satellites in chromosomal classification (now abandoned) and the relationship of long satellites to certain diseases which had been proposed on rather slender evidence.

The second chapter contains a most valuable contribution to the literature on chromatin-positive males (who do not necessarily, as Dr Court Brown points out, present with Klinefelter's syndrome), and a study of the ways in which they present for diagnosis and of their ultimate fate.

The third chapter deals with the Y chromosome; two findings of particular interest are the evidence that there may be a sex-determining locus on the short arm of the Y (this is based on the phenotypes of individuals found to have abnormal Y chromosomes) and the well known recent discovery of the high incidence of tall XYY males in institutions reserved for unusually violent and aggressive individuals.

In the last chapter the author considers chromosomal rearrangements in the population and relates them to the classical theories of Muller and others relating to radiation-induced rearrangements. Here again the main types of rearrangements found are catalogued together with their incidence, which totals (on the basis of mitotic studies) about 0.5 per cent in the normal population. The author indicates, however, that the recent meiotic studies of McIlree and others in the Clinical Effects of Radiation Unit show clearly that this figure is likely to be an underestimate, for they have brought to light probable heterozygosity in the chromosomes not visible in mitotic cells.

Altogether this is a monograph which will be essential in the library of any human geneticist or cytogeneticist. It gives the basic data on the incidence and genetic behaviour of such gross alterations in the autosomes as can be seen by microscopic inspection. Abnormalities of the sex chromosomes are not dealt with as a whole, because these were thoroughly documented in an earlier monograph from this unit. The layout of this work is particularly clear and easy for reference. Cytologists

may regret that the author has not gone more deeply into the biological significance of the chromosomal abnormalities described; into little-understood things such as heterochromatin or chromosomal coiling, or the whole problem of why the acrocentric chromosomes are so much more often involved than the others in rearrangements; but these matters were perhaps outside his terms of reference. The fundamental significance of this book is the sheer volume of research on which it is based. It is to be hoped that the possible computerization of chromosome analysis may enable the unit to undertake even more extensive studies in the future.

E. H. R. FORD

## QUALITY OF MILK

### Nutrition and the Composition of Milk

By Manfred Kirchgessner, Henning Friesecke and Gunter Kock. Translated from the German by Catherine T. M. Herriott. (International Monographs: Aspects of Animal and Human Nutrition.) Pp. xiv + 273. (London: Crosby Lockwood and Son, Ltd., 1967.) 55s. net.

THE factors controlling the composition of cow's milk are partly of genetic and partly of environmental origin. This book is primarily concerned with one of the most important of the environmental factors, the effect on the quality of milk of different feeds and methods of feeding. In the book, which is a translation of the German edition published in 1965, the authors outline the chemistry of the major constituents of milk and present comprehensive reviews of the influence of the diet on the physical properties of milk and on the content in milk of fat, protein, minerals and vitamins. The enzymes of milk and certain anomalous constituents, including antibiotics, pesticides and radionuclides, are discussed in the final chapters. A feature of the presentation is the large number of tables of compositional data.

The several thousand references cited in the text, mostly to work published within the past twenty years, bear witness to the considerable interest in these topics. Whereas some of this work was purely observational, much of it was carried out with the important immediate practical objective of maintaining and, if possible, improving the quality and thus the nutritive value of milk, particularly through increasing the content of non-fatty solids. At the same time advances in knowledge of the influence of the diet on microbial processes within the rumen and of the physiological and biochemical processes of milk secretion have facilitated a clearer understanding of the results of feeding experiments. The authors of this book have succeeded in drawing together the threads of knowledge in discussing the reasons for the effects of diet on the composition of milk.

With its very complete bibliography this book will prove a most useful work of reference and it is a worthwhile addition to this series of monographs.

J. W. G. PORTER

## JOURNAL FOR TAXONOMISTS

### *Journal of Natural History*

An International Journal of Taxonomic and General Biology. Vol. 1, Number 1 (January-March 1967). (Formerly the *Annals and Magazine of Natural History*.) Pp. 152. Price per part 52s. 6d. (\$7.50) plus postage. Subscription per volume (4 parts) £10 (\$28.60) post free, payable in advance. (London: Taylor and Francis, Ltd., 1967.)

It was in January 1952 that the *Annals and Magazine of Natural History* first appeared without the traditional pictorial design on its blue cover and so abandoned its dedication to lovers of nature. Now, as announced to

subscribers in a letter which was enclosed with the issue of last September, it has modernized itself in the manner of several other journals, even to the extent of changing its name. There will no doubt be mixed feelings. Some taxonomists will welcome this sign that their subject merits a journal with the same general appearance as those devoted to branches of the so-called "modern" biology. Others may be sad at the passing of an old friend. Librarians, always practical people, may curse the need to find a slightly taller shelf, but will be glad that the subscription price has remained unchanged, and that the numbers will now appear quarterly by intent as well as in practice.

The old journal was "conducted" by a distinguished list of experts. The new journal is edited by only two, with one assistant and an international panel of specialist consultants. It is a pity that we are not told who these are. The editor, in a note, says that it will now be possible to accept longer papers, and that contributions are invited on more general topics as well as the shorter papers on taxonomy and morphology that were a characteristic feature of the *Annals*. Like its predecessor, the *Journal of Natural History* remains the property of the publisher and is independent of any society or institution. The typographical format has been changed, the page size enlarged and the slightly tinted, loaded paper enables illustrations to be included in the body of the text. These changes should certainly lead to economies in production and to an improvement in the reproduction of the line drawings that are the most frequent form of illustration to this sort of communication. The practice does not, however, suit half-tone plates and the author may well be dissatisfied with the one example that appears in this first number.

The contents are of a high scientific standard, and include an important addition to the series of papers by Dr Sidnie Manton on the origin of the Arthropoda. The wide range of taxonomy is indicated by the fact that the ten other authors are drawn from university departments of botany, geology and zoology and from institutes of entomology, freshwater and marine biology as well as from the traditional museums. There is no doubt that knowledge of the range and form of animals and plants remains at the root of biological science, and can be ignored by biologists only at great loss both to themselves and the subject. It is to be hoped that all true natural historians will welcome this new journal and will see to it that it is never short of material for publication.

J. W. S. PRINGLE

## ANTIBIOTICS IN THE MAKING

### Biosynthesis of Antibiotics

Vol. 1. Edited by J. F. Snell. Pp. x + 234. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 80s.

THE first volume in this series provides a survey of the literature pertaining to the biogenesis of selected groups of antibiotics up to early 1966. The book is divided into six chapters, each covering a clearly defined topic, and each written by different authors. As a result, a different emphasis within each topic is readily apparent. Somewhat surprisingly the chemically more simple antibiotics such as D-cycloserine, chloramphenicol, griseofulvin, sarkomycin and L-azaserine are not dealt with as might have been expected in a first volume, especially because some of these compounds illustrate simpler versions of biogenetic pathways which are covered in the work.

The first chapter gives a rather superficial treatment of microbial processes which have been applied to the preparation of labelled antibiotics. The chapter is partly redeemed, however, by the excellent table of selected specific examples (where a strict adherence to alphabetical order would have been an improvement) and by the

comprehensive bibliography which provides ready access to more detailed material.

The second chapter, which certainly could have been better presented, deals with the biogenesis of the penicillins and cephalosporins and includes useful sections on penicillin acylases and the "semisynthetic" penicillins and cephalosporins. Particularly poor features, so far as students are concerned, are the complete lack of stereoformulae and the portrayal, in Figs. 2, 3, 5 and 7, of sequences of biochemical conversions solely by use of the names of the compounds involved. The presentation of formulae with individual asymmetric centres labelled D or L is no substitute for proper stereoformulae in the portrayal of absolute configuration, and structural formulae are essential for instant appreciation of chemical changes. Closer attention could have been given to analogy in organic chemistry of the reactions involved in the biosynthesis of the penicillins and cephalosporins, and the statement that cephalosporin P appears to be of steroidal nature in terms of a 1957 reference reveals a lack of breadth in literature coverage.

A better presentation is evident in the third chapter which covers the biogenesis of the tetracycline group. Here, as in the fourth chapter which deals with the biosynthesis of streptomycin, with very little mention of antibiotics chemically similar to streptomycin, stereoformulae are given, and due attention is paid to possible reaction mechanisms in the biogenetic pathways.

The fifth chapter seems completely out of place in this work, for it is concerned with a broad review of polyacetylene biogenesis with no apparent relevance to any specific antibiotics. Moreover, the introductory text which states that polyacetylenes have two main taxonomic loci in higher plants, of which only one is mentioned by name, is poorly married to Table 1 which shows four major loci, with the result that only an expert botanist could gain much from the discussion of the distribution of acetylenic compounds in Nature.

The sixth chapter, which deals with the macrolide antibiotics, is perhaps the best chapter in the book, with a good balance between biochemistry and reaction mechanism.

In summary, the book is rather uneven, and while it will serve as a valuable source of references in the library to workers in various biological fields it does not appear to be a book to inspire private purchase by graduate students or university staff members.

M. MARTIN-SMITH

## OBITUARIES

### Dr S. B. Challen

STEPHEN BENJAMIN CHALLENGER died at his home in Havant, Hampshire, at the age of 42. Educated at Queen Elizabeth's School, Blackburn, and the Blackburn Technical College, he served his pharmacy apprenticeship during the Second World War, and graduated from the University of London School of Pharmacy in 1947. After two years national service with the Royal Air Force he was appointed assistant lecturer at the School of Pharmacy and subsequently became a lecturer in 1951. He spent a year as visiting professor of pharmacognosy at the University of Saskatchewan and was appointed head of the School of Pharmacy at Portsmouth College of Technology on April 1, 1964.

Dr Challen was a pioneer in pharmacy education and was secretary, president and organizing secretary of the British Pharmaceutical Students' Association, and associated with the formation of the International Pharmaceutical Students' Federation. He had gained in 1952 a special degree in botany by part-time study; and his researches

on the chemical constituents of plants and the retention of pesticides on leaf surfaces reflected his interest in botany. His achievement in revitalizing the Portsmouth school and developing Council for National Academic Awards degrees and strong research groups represents his major work, and the future of the school based on the firm foundation which he laid will provide his best memorial. His death is a sad loss to pharmacy and to pharmaceutical education in particular.

W. DAVEY

### Professor Richard S. Schweet

RICHARD S. SCHWEET was killed in an air crash on April 3, 1967, at the age of 48.

He graduated BS at City College, New York, in 1938, and MS at Iowa State College in 1941. After military service during the Second World War he continued his research studies and graduated PhD in 1950. For the next two years he was a research fellow with D. E. Green at Wisconsin where he studied the properties and functions of pyruvic oxidase. He then moved to California Institute of Technology where he worked in the laboratory of H. Borsook, holding a senior fellowship from 1953 until 1958. During this period he initiated his studies on protein biosynthesis which he actively pursued until his premature death. In this field, which has moved forward extremely rapidly during the past decade, Schweet made many major contributions and was consistently at the forefront of ideas.

In 1958 he reported studies in which the soluble system for incorporation of amino-acids into RNA was resolved into an activating enzyme fraction and an RNA acceptor. His experiments supported the earlier proposal that there is a specific activating enzyme for each amino-acid and provided evidence that there is a specific RNA acceptor for each amino-acid. This was an important point in establishing that soluble RNA fulfilled the role of an adaptor molecule.

Later in the same year Schweet (with H. Lamfrom and E. Allen) reported the synthesis of haemoglobin in a cell-free system prepared from rabbit reticulocytes. This system provided the first example of the cell-free synthesis of a known soluble protein and its use has facilitated the elucidation of many aspects of protein synthesis. Studies, in collaboration with J. Bishop and J. Leahy (in 1960), using the reticulocyte cell-free system led to the conclusion that the peptide chain is synthesized sequentially from the amino terminus.

In 1960 Schweet went to the University of Kentucky Medical Center as full professor in the new department of biochemistry headed by Dr G. W. Schwert. There, with a series of collaborators, he studied many aspects of protein biosynthesis, including the role of transfer RNA, the steps involved in the transfer of amino-acids from amino-acyl RNA into protein, the functioning of polyribosomes and the action of various inhibitors of protein synthesis.

In 1964 Schweet published (with R. Arlinghaus and J. Shaeffer) important evidence showing that peptide chain growth occurs by the alternate action of two transfer enzyme fractions. The first fraction, requiring guanosine triphosphate, appears to function in the binding of amino-acyl RNA to the ribosome and the second (peptide synthetase) catalyses the formation of the peptide bonds as each amino-acid is added sequentially to the chain.

During 1965 Schweet left the department of biochemistry to become chairman of a new department of cell biology, and much of his time during the past two years was devoted to that venture. He served on grant reviewing committees for the National Institutes of Health and it was in this role that he undertook the fatal flight to Colorado. In the scientific world he will be especially missed by those who had the pleasure of collaborating with him and learning from him, and who thereby shared his warm friendship.

A. R. WILLIAMSON

## University News:

### Birmingham

THE following appointments have been made: Professor J. G. Hawkes, to the Mason chair and headship of the Department of Botany; Professor P. G. H. Gell, to the chair of experimental pathology and headship of the Department of Experimental Pathology; Dr D. B. Brewer, to the chair of morbid anatomy in the Department of Pathology. Mr P. M. Woodward, of the Royal Radar Establishment, Malvern, has been appointed to the honorary professorship in the Department of Electronic and Electrical Engineering.

### Leeds

DR E. ALLIBONE, chief scientist of the Central Electricity Generating Board, has been appointed external professor to the Department of Electrical and Electronic Engineering.

### Southampton

PROFESSOR T. E. H. WILLIAMS, professor of civil and transport engineering in the University of Newcastle upon Tyne, has been appointed to a chair of civil engineering; Dr E. W. Lee, reader in physics in the University of Sheffield, has been appointed to a chair of physics. The title of honorary professor in the Department of Mathematics has been conferred on Dr K. W. Mangler, deputy chief scientific officer in the Aerodynamics Department of the Royal Aircraft Establishment, Farnborough.

## Appointments

THE Minister of Technology has appointed Air Commodore C. S. Betts to be director of guided weapons research and development (air) in succession to Air Commodore R. R. Holder.

THE Minister of Technology has appointed Air Commodore H. A. C. Bird-Wilson to be director of flying (research and development) in succession to Air Commodore T. R. Pierce.

## Announcements

DR F. G. WALTON SMITH, director of the Institute of Marine Sciences at the University of Miami, has been elected chairman of the Executive Committee of the Joint Oceanographic Institutions Deep Earth Sampling Program.

THE administrators of the Sir George Beilby Memorial Fund, representing the Royal Institute of Chemistry, the Society of Chemical Industry and the Institute of Metals, have made an award from the fund of a gold medal and 100 guineas to Dr Anthony Kelly in recognition of his work in chemical engineering.

THE US National Academy of Sciences-National Research Council is accepting, on behalf of the James Picker Foundation, applications for post-doctoral awards of fellowships and grants in the field of radiology and nuclear medicine for the year 1968-69. The awards are made in the following four categories: Advanced Fellowships in Academic Radiology; Research Fellowships; Grants for Scholars; Research Grants. Further information can be obtained from the Committee on Radiology, National Academy of Sciences-National Research Council, 2101 Constitution Avenue, N.W., Washington, D.C.

## Meetings

PSYCHOTHERAPY—Prevention and Rehabilitation, August 21-26, Wiesbaden (Mrs Fay Pannell, Conference Services, Ltd., 11 Whitehall Court, London, S.W.1).

MARINE Biology, August 24-28, Norwegian College of Economics and Business Administration (Symposium Office, Biological Station, Espeyrend, Blomsterdalen, Norway).

INTERACTIVE Systems for Experimental Applied Mathematics, August 26-28, Washington (Juris Reinfelds, Computer Center, The University of Georgia, Athens, Georgia).

REACTIONS of Oxygen with Organic Compounds, August 28-September 1, San Francisco (Dr T. Mill, Stanford Research Institute, Menlo Park, California).

REPLICATION and Recombination of Genetic Material, August 28-September 1, Canberra (Dr W. J. Peacock, P.O. Box 109, Canberra City, A.C.T.).

SUMMER School on Quantitative Methods in Reflected-light Microscopy, September 19-23, Department of Mineralogy and Petrology, University of Cambridge (Mr G. A. Kingston, Department of Geology, Imperial College, London, S.W.7).

ERRATUM. In the note "Ice and Snow" in *Nature*, 214, 1073 (1967), it was stated that G. Ostrem and V. Schytt had spoken as chairmen of two working groups. In fact, they were reporting work carried out in their own countries—Norway and Sweden, respectively.

## THE NIGHT SKY IN AUGUST

All times are in Universal Time

		MOON		CONJUNCTIONS WITH THE MOON			
		New Moon	6d 03h	Venus	8d 01h, 10° S.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Tuesday, July 18

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W.1), at 5.30 p.m.—Annual Meeting.

Tuesday, July 18—Thursday, July 20

INSTITUTION OF ELECTRICAL ENGINEERS and the INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS (at the University of Manchester Institute of Science and Technology, Manchester, 1)—Conference on "Computer Technology".

Tuesday, July 18—Saturday, July 22

MEDICAL RESEARCH COUNCIL, MICROBIAL SYSTEMATICS RESEARCH UNIT (in conjunction with the COSPAR-IQSY Assembly, at Imperial College, London, S.W.7)—Symposium on "Sterilization Techniques for Instruments and Materials as Applied to Space Research".

Friday, July 21—Saturday, July 22

BRITISH ACADEMY OF FORENSIC SCIENCES (at the Institute of Psychiatry, The Maudsley Hospital, Denmark Hill, London, S.E.5)—Meeting on "The Hazards of Modern Life".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER IN PHYSICAL CHEMISTRY—The Registrar, University of Strathclyde, George Street, Glasgow, C.1, quoting Ref. 39/67 (July 19).

ASSISTANT LECTURER (with research interests in theoretical mechanics or pure mathematics) IN MATHEMATICS; and an ASSISTANT LECTURER IN STATISTICS—The Registrar, University of Strathclyde, George Street, Glasgow, C.1 (July 19).

ASSISTANT LECTURER IN HUMAN GEOGRAPHY—The Registrar, University College of Wales, Aberystwyth (July 20).

DEMONSTRATORS (3) (with a higher degree or equivalent postgraduate experience, and preferably experience in (a) mineralogy and petrology; (b) palaeontology; or (c) sedimentology and stratigraphy) IN THE DEPARTMENT OF GEOLOGY—The Registrar, The University, Newcastle upon Tyne, 2 (July 21).

LECTURER (with academic or industrial research experience in organic chemistry and/or experience in the application of physical instrumentation to the elucidation of problems of organic structure, and preferably a pharmaceutical qualification or experience of drug research) IN MEDICINAL CHEMISTRY—The Staff Officer (577/6), University of Aston in Birmingham, Gosta Green, Birmingham, 4 (July 22).

ASSISTANT LECTURER or LECTURER IN CROP AGRONOMY IN THE DEPARTMENT OF AGRICULTURE—The Registrar, The University, Nottingham (July 24).

DEMONSTRATOR/SENIOR DEMONSTRATOR (with a higher degree or equivalent postgraduate research experience, and preferably experienced in experimental entomology) IN THE DEPARTMENT OF ZOOLOGY—The Registrar, The University, Newcastle upon Tyne, 2 (July 24).

PROFESSOR (with interests in any branch of pure mathematics) to take charge of the division of PURE MATHEMATICS; and a PROFESSOR (with interests in any branch of applied mathematics) to take charge of the division of APPLIED MATHEMATICS, La Trobe University, Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, July 24).

JUNIOR RESEARCH FELLOW (with a good honours degree in physics and research interests in solid state physics) IN PHYSICS—The Registrar, The University, Sheffield (July 25).

CHAIR OF AFRICAN ANTHROPOLOGY at the School of Oriental and African Studies—The Academic Registrar, University of London, Senate House, London, W.C.1 (July 28).

SCIENTIFIC OFFICER (Bacteriologist) (with a degree in bacteriology or equivalent, and preferably practical experience of water treatment and of freshwater algae and fungi) to investigate bacterial diseases of fish—The Chief Pollution and Fisheries Officer, Trent River Authority, Meadow Lane, Nottingham (July 28).

LECTURER or ASSISTANT LECTURER (chartered civil engineer with a good honours degree) IN CONCRETE MATERIALS TECHNOLOGY—The Academic Registrar (LFG), University of Surrey, Battersea Park Road, London, S.W.11 (July 31).

MARINE ECOLOGIST (graduate with a research degree or equivalent experience) to join a research group studying present-day marine carbonate sedimentation processes off the west coast of Ireland—Dr A. Lees, Sedimentology Research Laboratory, University of Reading, Whiteknights, Reading, Berkshire (August 1).

CHAIR OF INORGANIC CHEMISTRY—The Registrar, University of Strathclyde, George Street, Glasgow, C.1, quoting Ref. 51/67 (August 5).

UNIVERSITY DEMONSTRATOR (with an honours degree in agriculture or agricultural science and preferably postgraduate experience of teaching or research in crop production) IN AGRICULTURE to demonstrate to classes on the University Farm, lecture and participate in research on crops—The Secretary, School of Agriculture, University of Cambridge, Downing Street, Cambridge (August 5).

RESEARCH FELLOW (with a degree in physics or engineering with Ph.D. or other postgraduate experience, and preferably an interest in aerodynamics or heat transfer, and computing) IN ENVIRONMENTAL PHYSICS for a group working on transfer of energy and matter in forest canopies using micrometeorological techniques—The Secretary, The University, Aberdeen, Scotland (August 6).

ENTOMOLOGIST (with a degree in agricultural science or equivalent and prepared to work in any part of New South Wales) IN THE DIVISION OF SCIENCE SERVICES, DEPARTMENT OF AGRICULTURE, New South Wales, to carry out research on insect pests—The Recruitment Section, New South Wales Government Offices, 56 Strand, London, W.C.2 (August 9).

ANIMAL TECHNICIAN (with appropriate training and/or experience) in the DEPARTMENT OF BIOLOGICAL SCIENCES, to be responsible for the day-to-day running of the animal house—The Principal, Lanchester College of Technology, Priory Street, Coventry (August 10).

LECTURER IN MATHEMATICAL STATISTICS at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office),

Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 11).

LECTURER and an ASSISTANT LECTURER in the DEPARTMENT OF PSYCHOLOGY—The Registrar, The University, Reading, Berkshire (August 12).

RESEARCH FELLOW (or in certain circumstances a Staff Fellow) in CHEMISTRY (Inorganic, Organic or Physical)—The Master, Selwyn College, Cambridge (August 15).

TEMPORARY LECTURER (preferably with interests in one or more of the following: urban, applied or social geography) IN GEOGRAPHY—The Registrar, The University, Newcastle upon Tyne, 2 (August 15).

DIRECTOR (with research experience in a field dealing with the production, processing and marketing of meat and meat products) of the M. C. FRANKLIN LABORATORY and WILLIAM MCILRATH FELLOW IN ANIMAL HUSBANDRY at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 18).

PROFESSOR OF PHYSICS at the University of Natal, Pietermaritzburg—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, August 18).

LECTURER IN HAEMATOLOGY and BLOOD TRANSFUSION in the DEPARTMENT OF PATHOLOGY, University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, W.C.1 (August 21).

RESEARCH ASSISTANT (preferably with an interest or training in electrophysiology, statistical methods or biochemical techniques) in the DEPARTMENT OF ZOOLOGY, to work with Dr D. M. Guthrie on the physiology of invertebrate nervous systems—The Secretary, The University, Aberdeen (August 26).

RESEARCH FELLOW (with medical qualifications) in the DEPARTMENT OF BIOCHEMISTRY, University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, W.C.1 (August 26).

LECTURER IN SOCIOLOGY at the Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 28).

SENIOR LECTURER/LECTURER IN ELECTRICAL AND ELECTRONIC ENGINEERING—The Registrar, University of Bradford, Bradford, 7, quoting Ref. EE/L/2/E (August 31).

LECTURER/SENIOR LECTURER IN MATERIALS SCIENCE at Monash University, Melbourne—The Academic Registrar, Monash University, Wellington Road, Clayton, Victoria, Australia; or the Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (September 1).

SENIOR LECTURER in the DEPARTMENT OF ANATOMY at the University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 2).

SENIOR LECTURER IN METALLURGICAL ENGINEERING in the DEPARTMENT OF METALLURGY, University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 30).

CHAIR OF EDUCATION—The Secretary and Registrar, The University, Southampton (October 9).

ENTOMOLOGISTS (2) (with an honours degree in biology with emphasis on entomology and practical postgraduate experience, preferably in biocontrol) for field work on biocontrol projects—The Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks (October 15).

FORBES CHAIR OF ORGANIC CHEMISTRY—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (October 31).

OFFICIAL FELLOW AND TUTOR IN PHILOSOPHY to teach ancient philosophy, and to take part in (or make arrangements for) the teaching of philosophy for the School of Philosophy, Politics and Economics and other honours schools—The Vice-Provost, Oriel College, Oxford (October 31).

ASSISTANT EXPERIMENTAL OFFICER or EXPERIMENTAL OFFICER (with a pass degree, H.N.C. or equivalent in an appropriate subject, and a general background of organic and physical-organic chemistry) to operate a combined gas chromatograph-mass spectrometer instrument in the new Meat Research Institute under construction at Langford, near Bristol—The Secretary, Meat Research Institute, Agricultural Research Council, Low Temperature Research Station, Downing Street, Cambridge, quoting Ref. CM 13.

CHAIR OF GEOGRAPHY—The Registrar (Room 39, O.R.B.), The University, Reading, Berkshire.

DEMONSTRATORS (preferably with an interest in the field of inorganic solvents, including liquid metals) IN INORGANIC CHEMISTRY—The Registrar, The University, Nottingham.

GAME MANAGEMENT OFFICER (normally national of the United Kingdom or the Republic of Ireland, with a B.Sc. degree in zoology and wildlife or equivalent, and preferably experience in wildlife management in East Africa and/or research into wildlife) IN TANZANIA, for duties which will include the planning, development and implementation of wildlife projects, and perhaps also the carrying out of scientific research into wildlife—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 275/267/01.

POSTDOCTORAL RESEARCH FELLOW at the Victoria University of Wellington, New Zealand, for work in the applications of Mössbauer effect to solid state reactions involving the development of high potentials—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1.

RESEARCH ASSISTANT to Professor J. E. Gibson in the DEPARTMENT OF CIVIL ENGINEERING to work in structural research sponsored by the Science Research Council. The research covers computer analysis of bridge, slab and shell structures and model and photoelastic experiments in this field—The Assistant Academic Registrar, The City University, St. John Street, London, E.C.1, quoting Ref. No. 8/CL.

RESEARCH ASSISTANT (with a degree or equivalent qualification) IN BIOCHEMISTRY to work on cation transport and the involvement of cations in metabolism—The Secretary, University College Hospital Medical School, University Street, London, W.C.1; quoting Ref. Ex.P.1.

RESEARCH ASSISTANT (with an honours degree in mechanical engineering or physics) in the DEPARTMENT OF MECHANICAL ENGINEERING to work on exciting new developments in the prediction of the fatigue life of metals—The Secretary, University College London, Gower Street, London, W.C.1.

RESEARCH FELLOW (with, or expecting to obtain shortly, a Ph.D. degree) IN SOLID STATE PHYSICS to work on the conducting and dielectric properties of thin films with special reference to switching phenomena—Prof. A. K. Jonscher, Department of Physics, Chelsea College of Science and Technology, Manresa Road, London, S.W.3.

STUDENT/JUNIOR TECHNICIAN (preferably with experience of histology) in a UNIT OF PHARMACOLOGY which has a special interest in the central nervous system—The Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London, S.E.5.

TECHNICIAN (young man or woman, preferably over 21 and suitably qualified) to assist in a programme sponsored by the Medical Research Council,

directed at understanding and improving the behaviour of materials used for surgical implants in the human body—The Staff Officer, University of Surrey, Battersea Park Road, London, S.W.11.

## HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

**\*12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire ..... **£14.0.0** each  
United States of America ..... (by air freight) **\$44** each  
Canada ..... (by air freight) **\$47.80** each  
Elsewhere overseas by surface mail ..... **£13.15.0** each  
(Charge for delivery by air mail on application)  
\*Shorter periods *pro rata*. (Minimum three months.)

### MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

**12 MONTHS** (52 issues and 4 indexes)

Number of Copies	G.B. & Eire	U.S.A. (by air freight)	Canada (by air freight)	Elsewhere (surface mail)
3-5	Each <b>£13.10.0</b>	Each <b>\$42</b>	Each <b>\$46.00</b>	Each <b>£13.10.0</b>
6-11	<b>£12.15.0</b>	<b>\$40</b>	<b>\$43.60</b>	<b>£12.15.0</b>
12 or more	<b>£12.0.0</b>	<b>\$38</b>	<b>\$41.70</b>	<b>£12.0.0</b>

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

### Editorial and Publishing Offices of "NATURE"

MACMILLAN (JOURNALS) LIMITED

## WONDER ELECTRIC MORTAR

INVALUABLE TO

**SPECTROSCOPISTS****GEOLOGISTS****AGRICULTURE RESEARCH****AND ALL ANALYSIS FIELDS**

**INFRA-RED  
EMISSION  
X-RAY**

- FASTER
- CHEAPER
- SIMPLER
- BETTER

### MIXING and GRINDING

**FORGET** tendency to cake, differences in hardness

**IMPROVE REPRODUCIBILITY** mixing and grinding are identical from sample to sample

**AVOID CONTAMINATION** plastic vials, caps, and ball pestles cannot introduce metallic impurities

**REDUCE EFFORT** entire assembly easily cleaned with mineral acids

**SAVE TIME** 10 seconds are sufficient for most samples

**SAVE SPACE** one vial used for weighing, mixing and storing

**SAVE MONEY** per sample cost is 4.2 cents—less than the cost of an ordinary container alone

With these new plastic and metal vials, the WIG-L-BUG is an indispensable tool in YOUR LABORATORY. The plastic vials are recommended for mixing powders or preparing mulls with mineral oil. For hard materials requiring grinding action use our metal vials, in which coarse sand can be ground to face powder consistency in one minute.

The action of the Wig-L-Bug is reciprocating in the form of a figure-8. Swung through a 6-1/2° arc at 3,200 R.P.M. the ball pestle thus strikes the ends of the vial some 2,000 times in ten seconds.

Prices Available on Request

**CRESCENT DENTAL MANUFACTURING CO.** 1837-1845 SOUTH PULASKI ROAD  
CHICAGO 23, ILLINOIS

### Classified Advertisements

Semi-displayed £4 16s. per single column inch. Minimum £2, each additional 1/12th of an inch 8s. Full page £132. Half page across £66. Colour (orange) £15 extra. 1s. is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, Strand, London, W.C.2. Telephone: 01-405 4743. Telegrams: Textualist, London, W.C.2.

### APPOINTMENTS VACANT

#### UNIVERSITY OF MALAYA DEPARTMENT OF GEOGRAPHY

Applications are invited for the following posts:

**SENIOR LECTURER** from population and/or settlement geographers with additional experience of research and teaching on population movements, settlement patterns and urban growth in south-east Asia.

**LECTURER/ASSISTANT LECTURER** in Surveying. A good degree in surveying is essential and the experience of research and teaching in photogrammetry would be advantageous.

**LECTURERS / ASSISTANT LECTURERS** (two) from urban geographers with additional experience in economics or from economists and demographers with interests in urban regional studies. The ability to apply quantitative techniques in the analysis of locational and distributional problems would be an advantage.

Salary scale (approximate sterling equivalent): Senior Lecturer, £1,890 by £70 to £2,310 per annum; Lecturers, £1,288 by £56 to £1,624/£1,680 by £63 to £1,995 per annum; Assistant Lecturers, £1,120 by £56 to £1,232 per annum. In addition the following allowances are payable: Variable allowance—35% of basic salary subject to certain maxima depending on marital status; minimum £210 per annum, maximum £560 per annum. Inducement allowance (if awarded) varies—(a) for Senior Lecturers, up to £560 per annum; (b) for Lecturers, up to £420 per annum; (c) for Assistant Lecturers, up to £280 per annum. Housing will be provided, if available, for which a rent of £140 to £175 per annum will be charged.

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1. The closing date for the receipt of applications in Kuala Lumpur and London is August 7, 1967.

(146)

## Meat Research

An important and challenging research post on meat packaging is available for a **CHEMIST, BIOCHEMIST** or **MICRO-BIOLOGIST** in the Animal Sciences Division of An Foras Taluntais (The Agricultural Institute). The person appointed will be required to carry out research on the problems associated with extending the shelf life of packaged fresh meat. Starting salary up to £2,465 depending on qualifications and experience. Marriage and children's allowances apply in addition. Pension scheme is non-contributory (special arrangements can be made in the case of an F.S.S.U. member) and working conditions are excellent.

**ESSENTIAL:** Honours University Degree or equivalent.

**APPLICATIONS ALSO CONSIDERED FROM 1967 FINAL DEGREE CANDIDATES.**

Further particulars and application forms from the Director, An Foras Taluntais, 33 Merrion Road, Dublin, 4, Ireland. Latest date for receipt of completed forms—August 21, 1967. (250)

## Scientific Civil Service

### MINISTRY OF TECHNOLOGY

#### NATIONAL PHYSICAL LABORATORY

##### DIVISION OF RADIATION SCIENCE

**PRINCIPAL SCIENTIFIC OFFICER** post for man or woman, preferably aged between 30 and 50, at the National Physical Laboratory, Teddington, Middlesex, involving responsibility for the current 2 MV exposure calibration service for radiotherapy and other purposes together with its future extension to protection-level exposure rates; also the development of absorbed dose and intercomparison services at higher energies, and collaboration on the installation of a linear accelerator facility.

**QUALIFICATIONS:** Normally 1st or 2nd class honours degree or an equivalent or higher qualification in an appropriate science subject. Knowledge of the work of hospital and health physicists and post-graduate experience in radiation dosimetry desirable.

**SALARY** (Outer London): £2,315 to £3,172. Entry may be above minimum for a candidate with qualifications and/or experience of special value. Promotion prospects to grades with national salary scales £3,500 to £4,000 and £4,175 to £4,625.

(Reference: S/6720/67.) Closing date August 9, 1967.

### MINISTRY OF AGRICULTURE,

#### FISHERIES AND FOOD

##### FISHERIES LABORATORY, Lowestoft

**MATHEMATICIAN** (graded E.O./A.E.O.; for man only) with background of biology or physical oceanography to join a computer systems team responsible for the transfer to an I.C.T. 1907 computer for most of the computational work called for by the laboratory's research programme; and the development of ship-borne computer systems aboard fisheries research vessels. Much of the work is in the field of fish population dynamics, physical oceanography and quantitative marine ecology. Once most of the transfer to the computer has been achieved the successful candidate will be switched into the general stream of the laboratory's research work. Participation in research vessel cruises involved. Previous experience in computer system analysis and/or programming desirable.

**QUALIFICATIONS:** Degree, H.N.C., or equivalent in appropriate subject. Under 22, minimum qualification is G.C.E. in five subjects; including two Scientific/Mathematical subjects at 'A' level or equivalent level.

**SALARY:** E.O. (minimum age 26) £1,365 to £1,734; A.E.O. £568 (at 18) to £803 (at 22) to £1,017 (at 26 or over) to £1,243.

Promotion prospects.

(Reference: S/579-580/MAFF.) Early application advised.

The above posts are pensionable and **APPLICATION FORMS** are obtainable from the Secretary, Civil Service Commission, Savile Row, London W.1. Please quote appropriate reference. (211)

#### UNITED NEWCASTLE UPON TYNE HOSPITALS

**PROBATIONER BIOCHEMIST** required for duties in the Department of Clinical Biochemistry. This is a joint University/Teaching Hospital department and a considerable amount of research work is undertaken. Candidates, who must possess an appropriate science degree will serve a probationary period before appointment to basic grade. Salary scale £855 to £1,210 per annum; after probationary period £1,040 to £1,658 per annum. Whitley Council conditions of service applicable.

Applications, giving full details of age, education, qualifications and experience (if any), with names of two referees to the House Governor and Secretary, Royal Victoria Infirmary, Newcastle upon Tyne 1. (223)

#### EAST ANGLIAN REGIONAL HOSPITAL BOARD

Cambridge Chest Clinic in conjunction with the Botany School, University of Cambridge

**RESEARCH ASSISTANT** for investigation of the daily and seasonal variation in the pollen and spore content of the atmosphere. Applicants should preferably hold an Honours degree in botany or equivalent technical qualifications and be willing to undertake a substantial amount of microscopy. Salary scale £850 to £1,150 per annum according to experience. Tenable for three years from October 1, 1967.

Further details from, and applications to, Dr. R. G. West, Botany School, Cambridge, by August 19, 1967. (215)

# Return to Research in Britain

Are you a British Scientist in North America thinking of returning to work in Britain? You may find what you are looking for, without having to go home first, in the Civil Service, the United Kingdom Atomic Energy Authority, or the Central Electricity Generating Board.

## Research Fellowships and Permanent Appointments

There are openings in most branches of science. The order in which they are most numerous is (i) physics, mathematics, engineering, and materials science; (ii) chemistry; (iii) biochemistry. The research ranges from the most fundamental to the most applied. Payment of fares (including family) to the United Kingdom will be considered.

### A Selection Board of scientists will be visiting centres as follows:-

WASHINGTON	-	8th to 22nd November, 1967
NEW YORK	-	27th November to 8th December, 1967
OTTAWA	-	16th January to 2nd February, 1968
CHICAGO	-	19th March to 5th April, 1968
SAN FRANCISCO	-	11th April to 8th May, 1968

If you would like to see them would you please write to one of the following at least six weeks, if possible, before the Board's arrival at the Centre nearest to you.

#### For Candidates in the U.S.A.

Mr. R.G. Voysey, Director,  
United Kingdom Scientific Mission,  
British Embassy,  
Washington 20008, D.C.

#### For Candidates in Canada

Dr. A. Huggard, Senior UKAEA  
Representative in Canada,  
P.O. Box No. 1245, Deep River,  
Ontario.

Issued jointly by the Civil Service Commission, the  
U.K. Atomic Energy Authority, and the Central Electricity Generating Board

# MATERIALS ANALYSIS

There are vacancies for Experimental Officers or Assistant Experimental Officers in the Materials Analysis Group of the Analytical Sciences Division, A.E.R.E., Harwell.

The Division has new laboratories equipped with a comprehensive range of modern instruments, and staff are given frequent opportunities to improve and widen their professional knowledge and are encouraged to publish original work. There are vacancies in two sections.

In the Spectrographic Section successful candidates will use the techniques of emission and atomic absorption spectroscopy to investigate the analytical problems arising from the study of a wide range of materials. They will also be required to assist scientists in the design and development of new spectroscopic instruments and methods. Some experience in analytical spectroscopy is desirable.

In the Physical Methods Section the successful candidate would work with a small group on instrumentation for chemical analysis. The work includes the development of new instruments and the elaboration of systems for the recording and reduction of data, and for automatic control and programming. Typical systems involve the use of operational amplifiers and logic circuits.

Training and/or experience in electronics is required, and the ideal applicant would also have subsidiary interests in computing and chemistry.

Applicants for Experimental Officer or Assistant Experimental Officer posts should preferably have a degree (or equivalent) but the minimum qualifications are G.C.E. in 5 subjects (including English Language at 'O' level and two scientific or mathematical subjects at 'A' level). The starting salary will be in the range £735-£1,335 (for an Assistant Experimental Officer) or £1,465-£1,860 (for an Experimental Officer), and will be related to age and experience.

Married officers living beyond daily travelling distance may in certain cases be eligible for Authority housing.

Please write for further details and application forms to:

**Personnel Department 'A' (519634),  
Atomic Energy Research Establishment,  
Harwell, Didcot, Berks.**

(199)

## UNIVERSITY OF NOTTINGHAM

### DEPARTMENT OF AGRICULTURE

Applications are invited for an ASSISTANT LECTURESHIP or LECTURESHIP in Crop Agronomy in this Department. The appointment will be effective from November 1, 1967, or as soon as possible thereafter. Salary will be within the range £1,105 to £1,340 (Assistant Lecturer) or £1,470 to £2,630 (Lecturer).

Forms of application and further particulars, returnable not later than July 24, 1967, from the Registrar. (208)

## ST. MARY'S HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON) PADDINGTON, W.2

Applications are invited for the appointment of

### LECTURER IN PHYSICS

for a period of three years, or TEMPORARY LECTURER for one year from September 1 or October 1, 1967. Consideration might be given to a part-time applicant. Commencing salary within the scale £1,470 to £2,270 to £2,630 plus London Allowance.

Applications (two copies), together with the names of two referees, should be sent by July 29, 1967 to the Secretary, from whom further particulars should first be obtained. (219)

## UNIVERSITY OF WESTERN AUSTRALIA

### SENIOR LECTURESHIP IN ANATOMY

Applications are invited for appointment to a Senior Lectureship in the Department of Anatomy. The salary range for the post is \$A6,500 to \$A7,600 per annum, plus superannuation similar to F.S.S.U.

The Department provides courses for undergraduate and postgraduate students in the Faculties of Science, Medicine and Dental Science. The position would best be filled by an Anatomist having training and an interest in research in the fields of Human Biology and Physical Anthropology. The appointee will be required to develop courses in Human Biology for third-year degree students in the Faculty of Science and would, as the department develops, be responsible for training postgraduate research students in association with the International Biological Programme (Human Adaptability Section). He will be expected to assist in the teaching of Gross Anatomy to Medical students.

The Department is currently undergoing expansion and will be moving into new buildings within two years. Existing research facilities include a laboratory for the study of ultrastructure equipped with a Philips E.M.300 high resolution electron microscope and necessary ancillary equipment. Further information concerning the Department may be obtained from the Head (Professor David Allbrook).

Intending applicants are requested to obtain details of the procedure to be followed in applying for the post and a copy of the appropriate conditions of appointment before submitting their applications. This information is available from the Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1. Applications close in Australia and London on September 2, 1967. (205)

## UNIVERSITY OF GLASGOW RESEARCH ASSISTANTSHIP IN DERMATOLOGY

Applications are invited from science graduates, either in chemistry or in biochemistry, for the post of Research Assistant. The successful applicant would be required to undertake work on the histochemistry of the skin with special reference to steroid synthesis. Salary scale: £1,105 to £1,340 per annum. Initial salary according to experience and qualifications. F.S.S.U.

Applications (three copies) should be lodged, not later than August 11, 1967, with the undersigned, from whom further particulars may be obtained.

ROBT. T. HUTCHESON,  
Secretary of the University Court. (261)

# Parasite Immunity

The Parasitology Research Department of the Therapeutics Research Division of Pfizer Limited is presently engaged in research programmes in the field of Parasite Immunity. Teams of scientists are working on basic and applied aspects of the problems related to animal and human diseases.

Two additional scientists are now needed to complete the teams.

## Immunologist

This appointment calls for a biological or chemical science graduate who has already gained some postgraduate experience in immunology, preferably in the areas of helminth and/or protozoal diseases.

## Parasitologist

This position involves fundamental work on the in vitro culture of helminths. Postgraduate experience is not absolutely necessary and new graduates will be considered together with those already possessing experience in this field or other branches of parasitology.

Both appointments offer the successful applicants excellent long-term career prospects. The starting salaries will be competitive and the fringe benefits generous.

Applications, which will be treated in the strictest confidence, should be addressed to:

**The Personnel Manager,  
Research Division, Pfizer Limited,  
Sandwich, Kent.**

(214)

## FIGHTING THE WRONG BATTLE

THE big guns of Imperial College have not chosen the happiest of moments for their protest at the difficulty of equipping their new laboratories (see page 341), which is not to say that they have nothing to complain about. To be sure, it is a modest misfortune that they now find themselves having to pore over their books of account in search of economies or extended credit much as if they were housewives overcommitted at the grocer's. It is also plain that the University Grants Committee has managed things badly, for the academic community as a whole has been badly informed about the change from one system of providing equipment to another. One problem is that too much protest about present difficulties may obscure the plain truth that the proposed change is in the best interests of the universities as a whole. Whether academic protests will strengthen the hand of the Minister of Education in his fight with the Treasury about allocations for the quinquennium which begins a year from now or, alternatively, persuade him to spend more of his energies on some other part of the educational system is another matter, but there is plenty of evidence that Mr Crosland will not be indefinitely sympathetic to the universities.

On the virtues of the new system which the UGC is seeking to introduce, there is very little argument. Hitherto it has been the practice for universities being endowed with new buildings to be given a capital grant to cover the cost of equipment as well. Traditionally, the UGC has operated this system generously—for several years in the recent past, the capital grant for furniture and equipment has been roughly a third of the cost of new buildings. In practice this has often meant that the newest university laboratories have also been the best equipped. The replacement of equipment in existing buildings has, by contrast, been a charge on the recurrent grant to the universities, and proposals for the replacement of equipment have often been at a disadvantage in the competition with other ways of spending academic money. Everybody will be better off if there is now a more orderly system for the replacement of old equipment and furniture, and if universities are provided each year with a sum of money related to the scale of their academic operations and not to the historical accidents of the building programme. This, indeed, was the view pressed on the UGC by a broadly based committee and endorsed by the Committee of Vice-Chancellors a year ago. Not the least of the benefits of the new system will be the sense of autonomy that universities should derive from it.

Why, then, is there so much irritation in the universities? One of the troubles is that it is a long time to

August 1968, when the new system will begin to operate. But it is also plain that the UGC has failed to explain as fully as it should have done how the new system will affect the individuals most directly concerned—the heads of university departments blessed with new buildings in the past two or three years. Probably the committee has put too much faith in the processes of communication within universities. Telling a vice-chancellor of a proposed change in regulations may seem to the committee to be the same as telling the university, but there is no way of making sure that the message will filter through. It would do no harm if the UGC took the fuss about equipment grants as a proof that better channels of communication within the academic system are an urgent need. It is also possible that the UGC has underestimated the extent to which the new system will alter the balance of power within universities between vice-chancellors and university departments. The old equipment grant was a kind of dowry for the head of a department moving to a new building. The new one will tend to be much more the gift of a vice-chancellor and his committees. Until there is some first-hand experience of how this system will operate, the chances are that heads of departments will be apprehensive.

Universities as a whole are likely to remain uneasy about their relations with the Government at least until the scale of UGC support for the period beginning in 1968 has been defined. The plan is that subventions for the next quinquennium should be defined by the autumn of this year, although it is plain from what the Secretary of State for Education and Science has been saying in public that he will be hard pressed to wring from the Treasury all the funds which he may consider to be necessary. In this connexion, it may be important that the academic year about to start is the first in which the immediate target of the Robbins Report—197,000 university places of all kinds—will be attained. Although there will be some growth of the university system in succeeding years, not least of all because the new universities are half-way through their natural growth, the Government will not be publicly committed to forced expansion after 1968. Left to itself, and with all the pressures of demand from other fields, nobody should be surprised if the British Government seeks to keep university spending on a tighter rein after 1968.

In the circumstances, what academics should really be worrying about is the character of university teaching in the decade ahead. Those who signed the letter to *The Times* are probably right in identifying the cold hand of Government restriction behind their present discontents about equipment, but they have probably

picked too small an issue on which to fight. It is a much more serious threat that the sense of parsimony now settling on the universities may put a stop to developments in university teaching which are essential if British universities are to remain respectable in the years ahead. It is particularly important that the need of more postgraduate teaching, recognized by Robbins, should now be translated into fact. There are plenty of opportunities, expensive in the immediate future but economical in the long run, for collaboration between groups of universities well placed geographically. There is a great and universal need to make experiments with new kinds of teaching equipment. It is vital that universities, or those universities which feel so inclined, should be free to make experiments with undergraduate courses lasting four years coupled with less stringent requirements of students on entry. The most immediate danger is that the coincidence of renewed financial pressure from the Treasury and the attainment of the Robbins goal will bring in a period of stagnation in British universities. To demonstrate that such an outcome would be disastrous is more important than paying bills on time. After all, it is always possible for universities to borrow from the banks.

## BURN MORE COAL

THE Minister of Power is not planning to produce a comprehensive statement of British fuel policy before the autumn, but its broad outlines were plainly to be seen in the long and repetitive debate on the coal industry which spanned Tuesday and Wednesday in the Commons this week. Briefly, Mr Richard Marsh has gone further than most of his predecessors to acknowledge that the decline of the British coal industry, which has been continuous for the past decade, will persist for several decades to come. But, like his predecessors, Mr Marsh has chosen to take the edge off some of the problems which need solving by providing further measures of protection for the coal industry. Against their better economic judgment, the electricity and gas industries are to be asked to burn an extra six million tons of coal a year between now and 1971, and the British Government is to subsidize them for doing so. The fact that the minister is planning to do more than his predecessors to tackle directly the social problems of a declining coal industry will not entirely make palatable this dubious decision.

A plain recognition of what is happening to coal is nevertheless a considerable public asset, even though the trends have been plain ever since the mid-fifties, when the potential economic advantages of nuclear power first became apparent. Then the annual production of coal from British mines amounted to more than 200 million tons in each of several consecutive years, and there were plenty of people willing to burn the coal. Although electricity generating stations were the largest single customer, their collective consumption was hardly more than 12 or 15 per cent of all the

coal produced in Britain. Since then, however, events have moved rapidly to the disadvantage of the coal industry. The most serious and persistent influence has been the high cost of mining coal from British coal seams. The immediate result has been enormously to stimulate the growth of petroleum consumption in Britain. In spite of various measures of discrimination against petroleum which are equivalent in aggregate to a tax of something like 40 per cent, it is an open secret now openly acknowledged by the minister that the electricity generating industry would have preferred to substitute oil for coal at several modern power stations. But coal has also in recent years been able to shelter behind a ban on imports of cheaper coal from overseas and a ready supply of capital from public funds. It is no wonder that Lord Robens has been exuding sweetness and light in the past few weeks, for even he cannot have been entirely sure that yet another brake on the decline of his industry would be provided. The result—or at least the hope—is that by 1971 the annual consumption of coal in Britain will amount to 155 million tons, and that the nationalized secondary fuel industries—electricity and gas—will consume well over half of everything produced.

Protection as such, of course, is not entirely outrageous, and governments are frequently justified in shielding new and potentially important industries from competition which may be too fierce for survival. But the protection of declining industries is more often a snare than an economic benefit—the attempts to keep the British cotton industry on its feet in the decades since the war are a vivid illustration of that. With coal, the evil consequence of too much protection is likely to be an inflated price structure throughout the fuel economy. Ironically, Mr Marsh will probably find this out for himself when he is required in the next few weeks to adjudicate on the price to be paid by the Gas Council for North Sea gas. His freedom to fight hard for a low price will be compromised, to say the least of it, by his readiness to support the domestic market at too high a level. At the same time he may find that he has artificially unbalanced the development of nuclear reactors in the critical years immediately ahead. The British nuclear power industry—which does not deserve protection even though the economic case for it is stronger than with coal—now needs a steady flow of orders on which to cut its teeth and firm incentives to keep costs low enough to be able to compete successfully abroad. By asking the power stations to burn more coal than they want to, the Government has probably done more harm than good.

It is entirely possible, of course, that further measures of protection are not a kindness for the communities which depend on coal, but merely a means of providing them with a false sense of security. For what is to happen after 1970? Will the British Government then be prepared to maintain an artificial level of demand for coal? And if not, will there be a sudden contraction of the industry? In the early seventies

it is entirely possible that the natural demand for coal could be more like 100 million tons a year than the 155 million tons now planned for. The traditional customers are melting away. In a few years there will be a demand for 70 million tons or so of coal each year from power stations now working or being built, a demand for 20 million tons or so of coking coal each year for making steel, and the rump of that traditional but anachronistic market for coal to be burnt on open hearths in people's houses. But who else will want to burn coal? And who else will be able to afford to do so? In all the circumstances, it might have been safer and in the long run kinder to the men concerned if the Government had sought to anticipate the changes which are now well under way and not to delay them. It would have made more sense to aim at a contraction from the present rate of production of 164 million tons a year to something more like 140 million tons a year or even less by the end of the decade, and then to have done whatever may be necessary to see that people and communities robbed of work are given other things to do.

## UNLUCKY STRIKE

COLUMBIA UNIVERSITY seems to have made a serious error of judgment in its decision to undertake the management of a new cigarette filter. Even if the filter turns out to be as effective in removing tar and other condensates from cigarette smoke as its inventor, Dr Robert Strickman, claims, the university will have some tedious explanation to provide. It is therefore important to be quite clear that nobody objects—or should object—to the university making money. The independent universities in the United States are respected as well as envied by similar institutions elsewhere. The way in which they are able to live by their own laws must naturally seem a great opportunity to others less favourably placed. The fact that they have chosen to devote so much of their resources to creative scholarship is a striking proof of their high-mindedness. In the last resort, their freedom is based on their financial independence. Yet there are some ways in which universities, however great, cannot live by the simple rules which govern commercial enterprises. There are some kinds of money which they should not make, and there are some ways of making money which they should avoid. Some of this seems to have been forgotten in all the ballyhoo attending the launching of the new filter on July 13.

In the first place, it is entirely mystifying that the university should have taken such trouble to make a great occasion out of its public announcement that Dr Strickman had been generous enough to transfer to the university most (though not all) of his rights in the new filter. Columbia knows enough about the ways in which newspapers work to know that it is almost impossible to hint that an important announcement on smoking and health is on the way without whipping up excitement. In the event, trading in

tobacco shares on the New York Stock Exchange was stopped between midday and the point later in the afternoon at which stockbrokers could inform themselves about the news which Columbia had to broadcast.

And that, of course, was a bitter disappointment. As yet, there is only the most sketchy information about what the filter may accomplish. At Columbia on July 13, both the President, Dr Houston Kirk, and Dr Strickman steadfastly declined to say what the new filter is made of, or how its supposed effectiveness has been demonstrated. With so little to say, it is unlikely that an ordinary commercial company would have been able to create quite such a sensation. Indeed, announcements of improved filters are frequently to be heard. When the New York Stock Exchange stopped trading in tobacco, that was as much a measure of respect for the university as a proof of the statement that the new filter "is 70 per cent more effective" in removing tar from tobacco than other filters now on the market. And in any case, of course, whatever tests there may have been in Dr Strickman's laboratory, it is exceedingly improbable that anybody has had time to carry out clinical tests of the extent, if any, to which the new filter can diminish the incidence of lung cancer.

But should a great university rely on income from tobacco smoking? This is one of the questions now to be asked. Perhaps the first, though the most trivial, thing to say is that the Chancellor of the Exchequer in Britain would immediately be lost if he were deprived of the revenues from tobacco taxes. There will also be echoes of the way in which the Church of England was frequently criticized, before and after the war, for collecting ground rents on houses in London which were known to be used as brothels. The truth is that in a competitive economy it is exceedingly difficult to demand that respected institutions should exercise restraint about investment which others are entitled to ignore, and for practical purposes, of course, few people would object if Columbia were now seeking to make a fortune out of speculation in tobacco stocks. It has exposed itself to criticism only because it has set up what could easily become an intolerable conflict of interest. People will now be tempted to suppose that Columbia in its wisdom has decided that the probable connexion between smoking and lung cancer is illusory. At the press conference last week, Dr Kirk seems to have acknowledged, ineffectually perhaps, that his announcement was not to be taken as a pronouncement that smoking, after all, is safe. He and his colleagues will have to go much further than this if they are to remove the false impression which will have been created by the link between Columbia and the filter—and if they are to conform with the tough new spirit of the regulations of the Federal Trade Commission on tobacco advertising. The trouble, of course, is that if Columbia now embarks, as it should, on a campaign to inform tobacco smokers that there is no evidence that filters bring immunity from lung cancer, it will be undermining the chances of commercial success for its new enterprise.

## NEWS AND VIEWS

### One Step Up

At the European Space Conference last week in Rome, it was unanimously agreed by the 18 countries present that the conference should become a permanent body with national representation at ministerial level and that it should meet "at least once a year". In future it is to have executive power as well as an advisory and co-ordinating function—its unanimous decisions will be binding on all member nations. Any nation belonging to one or all of the three institutions ELDO, ESRO and CETS (Conference for European Telecommunications by Satellite) becomes a member of the conference. It was accepted at Rome that it is "necessary and urgent" for Europe to be given a co-ordinated space policy but that "amalgamation of existing space bodies was not yet practicable". Instead, there is to be an advisory committee on programmes, under a French chairman, to "frame proposals for the establishment of a European space policy" with special reference to scientific and technical research projects and "useful" space activities, and consideration of the launchers required to carry them out. The committee will be chiefly concerned with communications satellites and "a meaningful scientific programme concentrated on activities few in number but opening up new prospects in the research area"—a form of words intended to mean projects which can stand comparison with American experiments in one way or another.

To balance the possible enthusiasm of the scientists and technologists, there is to be a second sub-committee to assess the viability of all proposals for the European economy as a whole. This committee has been asked to bear in mind that Europe has limited resources not only of money but also of trained manpower, and that a balance must be struck between the demands of a space programme and those of other more immediately profitable technologies, and that programmes should accommodate the real interests to consumers (particularly relevant for the communications satellite proposals).

The British delegation, led by Mr John Stonehouse, Minister of State at the Ministry of Technology, considered this machinery for economic screening of great value, but its immediate effect has been to postpone for perhaps nearly a year any decision on the European communications satellite project which has been the subject of a design study by ESRO on behalf of CETS. The project has now been hanging about for two years. ESRO has been voted a further £1 million to keep the communications satellite study team together until the end of the year. (The original contract placed last autumn was worth about £100,000.)

Another key project which has been waiting for a decision and must now undergo further screening is the Large Astronomical Satellite for which the Culham Laboratory was awarded the contract for the scientific equipment last August. Apart from administrative decisions, the project has been caught in the general

budgetary freeze which has afflicted ESRO this year because of the failure of member countries to agree to the organization's budget for its second three year period (1967–70). Last week's meeting has got ESRO temporarily moving again by releasing on British initiative £10 million of money underspent against the first budget for immediate use.

### Space Jamboree

IF all scientific conferences were as over-subscribed as the joint meeting between IQSY (International Quiet Sun Year) and COSPAR (Committee for Space Research) which is going on in London this week, the hotel business would have little to complain about. Instead of the expected 650 delegates, 1,000 turned up, forcing the organizers to change the venue from the Department of Mechanical Engineering at Imperial College to the Royal Geographical Society. The Royal Society, which is organizing the meeting, seems to have been left rather breathless by the task of catering for so many, but the slight air of disorganization at least adds more excitement and urgency to the meeting.

At the opening ceremony, there were plaudits for international scientific co-operation from Professor P. M. S. Blackett, Mr Anthony Crosland and (in a message read by Dr A. H. Abdel Ghani) the Secretary-General of the United Nations, U. Thant. Only Professor W. J. G. Beynon, President of the IQSY Committee, gave any hint how such co-operation might be prolonged now that the IGY and the IQSY are things of the past. There was, he said, a closely knit fraternity of geophysicists, who had been able to forget disciplinary and international differences, and at the very least they should try to maintain the central administrative machinery which had been developed. Perhaps, he suggested, this could be done through the new Commission for Solar Terrestrial Physics.

The meeting is really two meetings. The first, the IQSY meeting, from July 15 to 22, was concerned with an initial broad assessment of the IQSY. The second meeting, from July 24 to 29, the COSPAR meeting, will cover an enormous range of space research, including a symposium on sterilization techniques, and sessions on tracking, telemetry and dynamics of satellites, collection and detection of interplanetary dust, reviews of upper atmosphere structure and variations, and a seminar on stratospheric circulation.

### Sponsors Wanted

At least three large radio-astronomy projects are at present exercising the judicial capacities of the National Science Foundation in the United States. Each has asked the NSF for support, and it is most unlikely that there will be enough money to support all three.

Thirteen universities in New England and New York State have grouped together to form the Northeast Radio Observatory Corporation, a non-profit organization. They want to build a very large dish, 440 ft. in diameter, covered by a space-frame radome. The radome would need to be 550 to 600 ft. in diameter, and it is designed to be built of fibreglass sheets 40 thousands of an inch thick inside a steel framework. The blockage of the radio signal which the framework

will introduce will be equivalent to a reduction in the size of the dish from 440 to 400 ft., but it will offer a new freedom in design. The dish inside will be free from the effect of the wind, and therefore will need to be designed to withstand only gravitational forces. It can be built of very light alloy, and the distortion of the structure in different positions can be taken up by hydraulic jacks. It should be possible to operate the telescope at wavelengths down to 5 cm. The instrument will be mounted on a turntable, and carried on a horizontal beam with a row of bearings. The cost of the project—called Camroc—will be about \$25 million, and Dr Jerome Wiesner, Provost of MIT, has been elected chairman of the corporation which hopes to see it built.

In the West, there is another proposal for a large dish, this time 328 ft. in diameter. The project is supported by the University of Michigan, California Institute of Technology, Stanford University, and the University of California. Caltech has responsibility for the design, construction and ultimate operation of the instrument, which would be built at the Owen's Valley Observatory. The cost would be \$17.8 million, and again the NSF has been asked for support.

Meanwhile at the National Radio Astronomy Observatory at Greenbank there is a proposal to build a large array consisting of a series of smaller dishes. This project would be the most expensive, about \$50 million, but would cost a good deal less than an ambitious plan for a very large dish which was in the air at Greenbank some years ago.

## Fuss about Equipment

THE fuss over equipment grants for British universities has broken out again. When the row first surfaced in May this year, bursars complained that the transition to a new system for equipment grants had left their science departments so short of money that students would have to be turned away. At the time, the University Grants Committee explained (*Nature*, 214, 756; 1967) that the difficulty had been caused by the transition to the new system, and would soon resolve itself. Some university departments are now beginning to see much more discreditable motives behind the decisions. In a letter to *The Times* on July 17, Sir Cyril Hinshelwood and some of his colleagues from Imperial College claimed that the UGC had dishonoured firm pledges and gone back on financial commitments made in the past. Sir Cyril also saw a conscious decision to limit expenditure on equipment grants during 1967.

Ironically, there seems to be no doubt that the UGC has in fact provided more money for equipment this year than in 1966-67. The figures are £22.5 million for 1967-68, against £21.5 million in 1966-67 and £17 million in 1965-66. In any normal year, this would have been enough, but this year is the last before the new quinquennium. Grants awarded at the beginning of the quinquennium for equipment have in many cases not been entirely taken up by the universities; in the past, the UGC has found that it often takes universities 6 or 7 years to draw the whole of the grant. On April 1, 1967, this unspent balance held by the UGC amounted to £38 million, to which universities felt they were entitled. To this extent, the £22.5 million which the UGC coaxed from the Treasury does represent a

cut, of £15.5 million. The UGC says that this money will not be lost, but will go into the kitty when the new system starts to operate. The universities, on the other hand, may fear that if they do not get it out soon they will not get it at all.

The UGC claims to have foreseen the problem early in 1966 and to have discussed it with the Vice-Chancellors. The problem was again explained to the Vice-Chancellors in September 1966, and was the subject of a letter from Sir John Wolfenden to the universities in December 1966. In this letter, Sir John warned that it might be necessary to control the rate of drawings. In order to control the situation, the UGC decided to distribute the £22.5 million in two stages; £20 million in the first stage, leaving £2.5 million in reserve for universities which felt deprived. Universities were asked to make supplementary claims for this £2.5 million by June 31; when the claims came in, the UGC was alarmed to see that they amounted not to £2.5 million, but to £21.5 million. Clearly the reserve could not hope to keep the universities happy.

## Look, No Hands

IN the engineering industry it is estimated that about 40 per cent of the production time consists of putting together finished components to produce the final article for sale. In the motor industry, the figure is even higher—60 per cent on assembly, and only 40 per cent on metal working. Faced with these figures, it is perhaps surprising that there has so far been no coherent attempt to automate the assembly process, cutting costs and releasing men for other jobs.

The Ministry of Technology is now trying to catch up with lost time. The minister, Mr Wedgwood Benn, announced on July 18 three projects for the development of automatic assembly. The first is a development contract with Staveley Industries to which the ministry will lend £200,000 over three years for the design and development of units which can be used as a basis for producing automatic assembly machines. Staveley will not be attempting to produce complete machines—the intention is to develop modular units which can be fitted together in different ways to do different jobs. A simple machine might be made up of a bowl feeder which selects one part from storage, an escapement mechanism which offers the part up in correct alignment with other parts, and a screw driving head which connects the two parts together. No human intervention will be necessary.

The ministry is also thinking of providing financial support for the Institution of Production Engineers, which is to produce what are called production data memoranda. These will supply engineers with the critical data needed to make use of automatic assembly, and will also include the availability of equipment and the economics of application. The ministry intends to support work in universities, starting with the Department of Production Engineering at the University of Nottingham. Professor Heginbotham and his team will be investigating the methods used for packaging parts, and teachable machines. These are machines which can be taught to carry out assembly functions by being first taken through the job by an operator and storing the information in a memory.

They promise to be particularly flexible and thus suitable for small batch production.

## Brain Drain, Both Ways

THE Meteorological Office announced with considerable pleasure this week that Professor Raymond Hide, professor of geophysics and physics at the Massachusetts Institute of Technology, will be joining it in September of this year. Professor Hide graduated from the University of Manchester in 1950, took his doctorate at Cambridge in 1953, and became a lecturer at the University of Newcastle. He was appointed a full professor at MIT in 1961 at the early age of 32, and is well known for his work on fluid motions in the atmosphere, the Earth's core and the atmosphere of Jupiter. A special senior post has been established in the Meteorological Office for Professor Hide, who will be in charge of a new laboratory of geophysical fluid dynamics.

Dr John Napier of the University of London is going the other way across the Atlantic. He has been appointed by the Smithsonian Institution in Washington to investigate the possibility of establishing an International Center for the Study of Primate Animals. Dr Napier, a leading authority on primate biology, will be trying to plan programmes for the best training of primate biologists on both sides of the Atlantic, and will also be studying primate classification, morphology, anatomy, genetics, palaeontology, ecology and behaviour.

## Who Does What

THE Department of Education and Science and the British Council have produced their guide to *Scientific Research in British Universities and Colleges* (HMSO, Vol. I, Physical Sciences, £2; Vol. II, Biological Sciences, £2; Vol. III, Social Sciences, £1 12s. 6d.) at the end of the academic year to which it relates. Although the great value of this publication may be somewhat tarnished by the fact that roughly 10 per cent of those listed in it may have moved to universities other than those to which they are said to be affiliated, or may have changed their research projects, it remains a considerable achievement that this compendium should be published at all. This year, the volumes are somewhat more free from error than is usually the case. The subject index remains wayward, with some coarsely defined categories and some defined in great detail. The character of descriptions of research projects varies enormously from one university to another—some spell out what individual members of a department do and some still include them all under one great umbrella.

The social sciences volume breaks new ground by including among the institutions with which research projects are identified organizations which are not strictly universities at all—the London Transport Board, for example, the Central Office of Information and the Shirley Institute. Apparently the publishers would be prepared to include in this volume details of work carried out in industrial establishments. The future of the other compilations will depend on a survey being carried out by the Office of Scientific and Technical Information. Potential users in universities and government departments have been asked to

specify the kinds of enquiries they would like to see made. One possibility is that a magnetic tape index to the volumes will be produced, and that the work of government establishments may be lumped in with that of universities. There seems as yet no prospect that industrial research in the full-blooded sense will be included.

## More Plans for Food

ANOTHER attempt to provide policies for feeding the world population has been made, this time by a committee which advises the Economic and Social Council of the United Nations. The Advisory Committee on the Application of Science and Technology to Development, under whose aegis the report is published, has been advised by a series of sub-committees, expert panels, and working parties, but it seems that responsibility for most of the recommendations rests with a small group of three: Dr W. F. J. Cuthbertson (UK), Dr D. S. Bhatia (India) and Dr A. A. Pokrovsky (USSR).

The committee has concentrated on one aspect of the problem, increasing the production and use of edible protein. Unfortunately it has come up with some rather well worn suggestions. Protein from conventional sources should be increased, using modern technology, and should be supported by better use of marine and inland fisheries. The committee also sees a role for unconventional sources of protein; soya, peanuts, and textured vegetable products are all given a favourable mention. Fish protein concentrate (fish meal) can also contribute, the committee feels, and it recommends greatly intensified research on single cell protein sources, which can be produced without using agricultural land. There are also recommendations about research, training and marketing.

The report will be debated by the Economic and Social Council at its meeting this month, which has in the past been a signal for similar reports to disappear without trace. This time the committee has made a worthwhile attempt to cost its proposals, and some of them are surprisingly modest—\$5 million annually to prevent waste, for example, or \$5 to \$8 million a year over the next five years to set up regional centres for research and training in agricultural technology and food science. One problem which the report ignores—in common with almost all reports of this kind—is the effect of the price structure on food production. Until producers, distributors and retailers can go ahead with full confidence of making profits from their work, nothing is likely to come of the plans. This, perhaps, was what President Johnson's Science Advisory Committee was hinting at in its report on food production (*Nature*, 215, 234; 1967) when it said that few countries were making full use of the power of the market economy.

## Rockefeller against Hunger

THE Rockefeller Foundation remains dedicated to the problems of food and population in developing countries. According to Mr J. G. Harrar, the president, in his review of 1966, out of a total spending of \$31.9 million on the foundation's five principal areas of interest \$8.6 million was spent on the programme called 'Towards the Conquest of Hunger' and \$3.8

million on 'Problems of Population'. The foundation also spent \$7.8 million on university development, \$3.3 million on 'cultural development' and \$4.9 million on 'equal opportunity for all'.

Mr Harrar points out in his review that all efforts to provide food and other material requirements will fail unless the rate of world population increase can be significantly reduced. The Rockefeller Foundation adopted the 'Conquest of Hunger' as one of its principal objectives in 1963. Important grants in this area during 1966 included one of \$533,000 for five years to the University of Nebraska Foundation for research on the physiology of sorghum yield and sorghum management, and another of \$100,000 for a three year period to the US National Academy of Sciences, for a multidisciplinary research and training programme, administered by the Africa Science Board's Subcommittee on the Development of Water Resources.

Much of the foundation's effort in the problems of population has gone into demography. Among the grants awarded were \$350,000 for a two year period to the Population Council, New York, for an international study of the effectiveness of family planning measures undertaken in the postpartum period, and \$400,000 for a three year period to the University of North Carolina for the preparation of educational material on population and the development of a computerized information retrieval service.

## Teaching Abroad

AN exhibition to introduce teachers in developing countries to recent advances in British science teaching has been organized by the British Council under the title of "New Approaches to Science Teaching". The emphasis of the exhibition is on teaching pupils to discover for themselves and thus to learn by understanding. With such an emphasis it is hardly surprising that the displays lean heavily on the Nuffield Science Teaching Project and the Scottish Education Department for their material. The exhibition covers the teaching of science in junior and secondary schools, and includes records and films. The organizers hope that the exhibition will encourage teachers in developing countries to evolve their own projects using local materials; from this point of view it may be a handicap that the contents of many of the displays are so western in character, from the examination question about tube trains to the projects on English insects. Nevertheless this exhibition, which goes first to Nigeria, will doubtless do a lot to advance science teaching in underdeveloped countries.

## Museum for Stargazers

THE £84,000 spent by the Ministry of Public Building and Works on the restoration of the Meridian Building at the Old Royal Observatory, Greenwich, is money well spent. The building has been restored to all its former glory, with the rooms and instruments reinstated, as far as possible, as they were used. The building, part of the National Maritime Museum, was opened to the public last Wednesday (July 19) by Sir Richard Woolley, the Astronomer Royal. Its history of nearly 300 years in the forefront of astronomical and navigational discovery is well presented for all types of visitor, from the package-tour rusher to the

serious student. It contains Airy's transit circle room from which the Prime Meridian is defined. Some visitors will be a little startled to find that there are, in fact, three meridians: Flamsteed's of 1681, Bradley's of 1750 and Airy's of 1850. Most of the instruments shown are the original ones used by the various Astronomers Royal. They include Bradley's 8 ft. Mural Quadrants, Airy's Transit Circle, Halley's Transit and many others, all tributes to the design and workmanship which made accurate observations possible.

## Progress in Welding

THE annual report of the British Welding Research Association for 1966 makes confident reading. The past year, as well as showing a significant growth in membership and research facilities, has brought better grant conditions from the Ministry of Technology. The ministry is now prepared to contribute 150 per cent on subscription income instead of the standard 100 per cent, up to a maximum of £350,000. Income last year was £644,487, an increase of nearly £80,000 over 1965. Expenditure increased by £105,000, to £614,363, and BWRA employs about 150 technical staff, almost half of them graduates.

A large part of the association's income is spent on advisory and liaison services. This includes visits by members of staff to member firms to advise on problems, and the information service run by the association. The most interesting problem studied by the information service during the year was the brittle failure of a pressure vessel while still under test at the manufacturer's works. Another investigation was one carried out for Samuel Fox and Co., Ltd., which showed that a new series of austenitic stainless steels (Hi-proof 316) developed by the company are suitable for pressure vessels, and offer considerable savings in cost and weight.

Much of the work was naturally concerned with welding processes. One of the largest friction welding machines in the world was designed and built during the year. In friction welding, a rotating piece is brought into contact with a stationary piece under pressure. The heat generated causes the two to bond, and the association reports that the technique is now being used industrially for welding turbine wheels to shafts and valve heads to shafts. In the metallurgical laboratories, work has gone on on burning and hot tearing in structural steels, and the avoidance of embrittlement and stress corrosion in welds in high strength aluminium alloys. A considerable amount of work on brittle failure seems to have been carried out, chiefly because brittle fractures are almost invariably initiated from weld defects.

## Preservation by Co-operation

IN an effort to educate gamekeepers and anyone else who goes to the country to shoot predatory animals the Council for Nature, in association with the British Field Sports Society, the Fauna Preservation Society and the Game Research Association, has produced a booklet *Predatory Mammals in Britain*, a code of practice for their management (The Council for Nature, price 5s.). The booklet was prepared by a working party—set up at a conference on mammalian predators in Britain in 1965—whose members represented con-

servationists, sportsmen and gamekeepers. Professor H. R. Hewer, the chairman of the Council for Nature, has described this co-operation as "a triumph of common sense", for the naturalists have agreed that predators must sometimes be killed, and the sportsmen have accepted that they can protect their game without eradicating all the predators.

The booklet contains illustrated notes on recognition, distribution, behaviour and control of twelve British predatory mammals. The need for control is clearly stated—the mink, for example, is potentially very destructive and should be eradicated; the hedgehog can cause serious losses of nests on a partridge beat, but elsewhere there is no need for control; the pine marten is virtually harmless, and although the otter can damage fishing interests it is doubtful whether it does much harm in Great Britain as a whole. The appropriate methods of control are given for each animal; the mole, which is an agricultural pest, proves particularly difficult to exterminate, and the working party has had to recommend poisoning with strychnine hydrochloride, although it had hoped to eliminate this poison from the countryside. Chapters on the law explain the methods of snaring, trapping, gassing and poisoning which can be used, and also the most humane ways of carrying these out. In a chapter prepared by the Universities Federation for Animal Welfare the best ways of killing trapped animals are described.

The working party is hoping to see *Predatory Mammals in Britain* in the pockets of all gamekeepers and sportsmen, perhaps an unduly optimistic target. In any case, these people may prove difficult to persuade. Promotion of the booklet in schools, which is planned, may help to produce a new, educated generation of gamekeepers and sportsmen.

## Radiological Committee

THE British Committee on Radiological Units has been reconstituted under the title of the British Committee on Radiation Units and Measurements by the Radioactive Substances Advisory Committee. It will be chaired by Professor F. W. Spiers, professor of medical physics at the University of Leeds and honorary director of the MRC Environmental Radiation Research Unit, and based at the National Physical Laboratory.

The committee consists of experts, serving in a personal capacity, who are actively interested in the quantitative use of radiation and radioactive substances in industry, science and medicine. It will act in an advisory capacity to government departments and other bodies, interpret ICRU recommendations, make recommendations to the ICRU and other bodies, and also set up forums and working parties for specific purposes.

## Design for Astronomy

THE Optical Group of the Institute of Physics and the Physical Society and the Royal Astronomical Society picked the right time to hold a conference on Astronomical Optics, at Imperial College last week. With astronomical telescopes promised at Kitt Peak in Arizona, Cerro Tololo in Chile, and in Australia, the next few years are bound to be full of interest in telescope design. The conference covered a wide field, some of it directly concerned with the new instruments.

One preoccupation is the possibility of replacing photographic recording by photoelectric methods. Among advantages this would confer are a higher quantum efficiency, a wider range of wavelengths covered and a linear response, as Professor J. D. McGee from the Department of Physics at Imperial College explained. The snag is that the equipment is heavier and more complex than the simple photographic plate. Professor McGee suggested four possible systems: television cameras, solid state detectors, electronographic tubes and image intensifier tubes, and went on to discuss his own speciality, cascade tubes with thin mica windows. Professor M. A. Lallemand from the Paris Observatory was hopeful that the electronic camera could achieve sensitivities ten to a hundred times greater than photographic emulsion, and offered more reliable and precise measurement. Dr M. J. Smyth from the Royal Observatory at Edinburgh described the working of the twin 16 inch photoelectric telescopes at the observatory. One telescope continuously monitors light from a reference star, while the second measures actual stars of interest within a  $10^\circ$  diameter field. In this way the reference beam can be used to compensate for changes of atmospheric transparency, an inherent limitation for ground based observations.

For the new large telescope projects, the Richey-Chretien optical system which gives an aplanatic secondary focus is being adopted in preference to the Newton-Cassegrain layout. Dr C. G. Wynne of Imperial College discussed what the change involves and described his own development of extended field systems which will be adopted on the new telescopes. Dr E. H. Richardson of the Dominion Astrophysical Observatory in Canada described the design of spectrographs for the Queen Elizabeth II 156 inch instrument proposed in Mount Kobau, British Columbia. Dr E. H. Linfoot of the observatories at the University of Cambridge discussed coma tolerances for photographic star images. Coma is an aberration produced when oblique rays falling on the same zone of the mirror are not brought to coincidence in the focal plane; the two mirror Richey-Chretien combination avoids comatic aberration, but suffers from astigmatism. Because of the non-linearity of photographic response, coma tends to shift the mean centre of the image of stars by a distance depending on the stellar magnitude, giving rise to systematic errors in the determination of star positions. Dr Linfoot, with Professor R. O. Redman, has attacked the problem of tolerances with a computer, and explained how his results affect telescope design.

There were several contributions concerned with astronomy from rockets or satellites. Mr R. H. Christie of AWRE, Aldermaston, has designed a system for an all-reflecting satellite telescope in which stability of image is maintained by rotation of the secondary mirror, controlled by a signal derived by a sensor placed near one image point. The advantage is that only a small mass need be moved to maintain alignment, instead of the entire spacecraft, and the telescope can be made independent of the guidance electronics of the spacecraft. Several speakers described spectrographs for rocket-borne studies, and Mr C. T. Farr from RAE, Farnborough, described a small photometer to be carried in a rocket. On the last day, Dr R. Q. Twiss of the National Physical Laboratory gave an

account of the stellar intensity interferometer at Narrabris, Australia, with which the angular diameter, and hence the radiation temperature of hot bright stars can be measured. Dr P. J. Trianor from the Vatican Observatory at Castel Gondolfo showed how he had measured the angle of polarization of stars. His method enables the statistical distribution of angles of polarization to be measured from one exposure.

## Four Classes of Microtubules

from our Correspondent in Cell Biology

ONE of the problems that continually faces electron microscopists is deciding whether organelles with the same fine structure have identical chemical composition and cellular function. Usually, the more complex the structure of the organelles, the easier it becomes to make this decision. Few would question, for example, that mitochondria and chloroplasts seen in different cells perform the same cellular functions. But does this apply to structurally simple organelles such as microtubules? Are they identical? According to Behnke and Forer (*J. Cell Sci.*, **2**, 169; 1967) there are at least four classes of microtubules.

Microtubules, simple cylindrical structures a few hundred angstroms in diameter and up to several microns long, are thought to be a virtually ubiquitous cell organelle. They occur in specifically arranged aggregates in cilia, flagella, sperm tails and the mitotic spindle, but also occur free in the cytoplasm without any obvious pattern of arrangement. The latter are known simply as cytoplasmic microtubules. Their function remains a mystery although various pieces of circumstantial evidence have led to a host of more or less likely suggestions: involvement in cell motility, cytoplasmic streaming, skeletal support, cellular plumbing, and the like. Surprisingly, however, despite all these proposed functions, it has generally been held that all microtubules are the same.

Now Behnke and Forer report that treatment of crane fly spermatids, rat sperm and rat tracheal cells with pepsin, colchicine, or storage at 0°C or 50°C clearly differentiates four classes of microtubules. In crane fly spermatids the cytoplasmic microtubules and those in the 9+2 arrangement, the central pair and each tubule of the nine outer doublets of their sperm tails respond differently to these treatments. Behnke and Forer conclude that these four classes have intrinsic differences in their chemical and/or physical composition. Furthermore the same four types occur in rat sperm and rat tracheal cells.

When examined after negative staining these four types of tubules have identical substructure. It appears that despite other differences, microtubules are in general constructed to a basically similar pattern, and Behnke and Zelder (*J. Ultrastruc. Res.*, **19**, 147; 1967) present more evidence of this. They have examined the substructure of the microtubules in mammalian blood platelets, which, like those in many other cell types, are labile to osmium tetroxide fixation but are preserved by glutaraldehyde fixation. They find the structure of these G-tubules is very similar to that of O-tubules, microtubules fixed by both osmium and glutaraldehyde. The wall of both types is constructed of about twelve fine filaments each about 35–40 Å in diameter and arranged in a cylinder with a 60 Å centre to centre distance.

## Parliament in Britain

### University Computers

THE Secretary of State for Education and Science, Mr A. Crosland, stated that purchase of computers for universities to the total value of £6.5 million had been approved so far against the programme outlined by the Flowers Committee, which was being kept under review by the Computer Board. Further major provision was under consideration by the board. It was still expected that expenditure in the first three years would average about £3 million a year when account was taken of building and operating costs. Expenditure by the research councils on "off line" computers totalled nearly £2 million in 1966–67 and was expected to be £1.5 million in 1967–68. (Written answer, July 12.)

### Teachers

REPLYING for the Government in a short debate in the House of Commons on July 10 on regulations for the training of teachers, the Minister of State, Department of Education and Science, Mr G. Roberts, said that full-time staff in the colleges now numbered 7,900. He agreed on the need to attract more graduate teachers in mathematics and science. The target was now 110,000 teacher training places, outside the universities, in England and Wales in 1973–74 and 100,000 by the end of this decade, the latter figure corresponding with an annual intake of 35,000 at a cost of £68 million in 1966–67. Since 1962–63 the number of new entrants had increased from about 5,000 to 9,500 but was still only about 28 per cent of all entrants, instead of the desired 35 per cent. The number of entrants aged 25 and more trebled between 1962–63 and 1966–67, when it reached 6,100. The proportion of those trained who left teaching was probably well below 3 per cent. On consultative machinery a wide range of views had been expressed and it would not be easy to reach a conclusion which would be universally acceptable. The Weaver report had been generally welcomed, and colleges of education had been invited to prepare schemes of government and provided with models from which they could work. Schemes were coming forward, but it was not intended to seek to impress any rigid uniformity in the articles of government. A modern scheme of government for voluntary colleges had also been agreed with the voluntary bodies and circulated to all colleges, and they were now submitting their proposals for new schemes of government. Mr Roberts hoped both types of college would emerge with the fullest possible academic and student autonomy appropriate to their nature. (House of Commons, July 10.)

### Steelworks

MR ARTHUR BOTTOMLEY, Minister of Overseas Development, gave details of the aid provided by the British Government for the development of the Durgapur Steelworks in India. Loans totalling £68 million had been offered since 1957, he said, and £60 million of this had so far been taken up. The expansion of the steelworks from 1.6 to 3.4 million tons had been postponed because the project was too expensive for the Indian Government, and the growth of the steel market in India had been slower than anticipated. Before expanding, the Indian Government wanted to attain full production at the existing capacity, he added. (Written answer, July 12.)

# Organochlorine Pesticides in Antarctica

by

J. O'G. TATTON  
J. H. A. RUZICKA

Laboratory of the Government Chemist,  
Cornwall House, Stamford Street,  
London, S.E.1

The first reports of organochlorine pesticides in wildlife in the vicinity of the US Antarctic base at McMurdo Sound suggested that local human activity might be responsible. Measurements of samples from the British Antarctic Survey Base at Signy Island in the South Orkneys now suggest that there is a world-wide pattern of distribution by means of the oceans and the atmosphere.

CONSIDERABLE interest was aroused in 1965 by news from the United States that DDT had been discovered in Antarctic wildlife. Details of this finding were given later in two papers. The first of these by Sladen *et al.*<sup>1</sup> described the detection of DDT and two of its toxic metabolites, DDE and TDE, in six Adèle penguins (*Pygoscelis adeliae*) and one crab-eater seal (*Lobodon carcinophagus*). All these specimens were taken at Cape Crozier on Ross Island (Fig. 1). The second paper by George and Frear<sup>2</sup> described a more ambitious study of samples taken on Ross Island and in the nearby McMurdo area. DDT only was detected in four out of sixteen Weddell seals (*Leptonychotes weddelli*) and four out of sixteen Adèle penguins. Of sixteen skuas (*Catharacta skua maccormicki*) examined, nearly all contained DDT and DDE. No pesticides were detected in water and snow samples, nor in samples of four phyla of marine invertebrates and an Emperor penguin (*Aptenodytes forsteri*). Of three species of fish taken in the Ross Sea, only one specimen of *Rhigophila dearborni* contained DDT but no DDE.

These discoveries suggested that the contamination of the environment by the new persistent organochlorine pesticides had spread to what is usually regarded as the most remote and isolated part of the Earth. The nearest land mass to Antarctica is Cape Horn in South America (Fig. 1), about 1,000 km distant, and most other land masses are at least 2,000 km away. The character of Antarctica is such that the only human residents on the continent are explorers and research teams, but the traffic of men and supplies brings visiting airmen and sailors to the region. Although the number of men on the continent has grown in recent years<sup>3</sup> and at times there may be as many as 4,000, the population is still minute relative to the land mass of about 13 million sq. km. There are no insect pests in the Antarctic and therefore no need for

insecticides. Moreover, there is a general international agreement, under the Antarctic Treaty of 1959, that Antarctica shall remain a faunal and floral preserve and that the existing ecosystems shall not be disturbed by, for example, the introduction of alien species or such powerful influences as pesticides. The detection of DDT in Antarctic wildlife therefore raised immediately the problem of its origin.

Both of the above reports referred to samples taken in the area served by the large United States base at McMurdo and it is perhaps significant that only DDT, and its first two metabolites DDE and TDE, were detected. It is now well known that the air and coastal waters of, for example, the United States and the British Isles contain traces of organochlorine pesticides<sup>4-9</sup> so that pesticides could have reached Antarctica by way of these two media. Air, rain and coastal waters, however, usually show traces not only of DDT and its metabolites but also of other organochlorine pesticides in common use, such as BHC and dieldrin. None of these other pesticides was detected in the samples from the McMurdo area. Therefore, there was always the possibility that no matter how vigilant the authorities concerned may have been, DDT had reached McMurdo simply because man himself had transported it there in his ships, food, clothing or stores.

If this latter supposition were correct, then other areas of Antarctica outside the environment of McMurdo might still be free from contamination. It was considered that this could be investigated by sampling in the area of the British Antarctic Survey Base at Signy Island in the South Orkney Islands (Fig. 1) some 4,500 km from the American base at McMurdo. If no DDT were detected there, then it would suggest that the contamination in the McMurdo area was directly due to local human activities. If DDT were found on Signy Island then again it might be

attributed to human activities but it would also reinforce the argument that there was general contamination of all Antarctica whether sea-borne or air-borne or both. The British Antarctic Survey generously agreed to co-operate in obtaining suitable samples from the Signy Island area and to transport them to England in a permanently frozen condition.

The samples included the livers, blubbers, abdominal fat and stomach contents of a number of chinstrap penguins (*Pygoscelis antarctica*). Most of these were adult birds, 3-8 years old, at the end of the breeding season when they were moulting and very fat; three of the birds were described as immature but at least 1 year old. The samples also included three penguin eggs, probably chinstrap, the fat and livers of two brown skua and two blue-eyed shags (*Phalacrocorax atriceps*), and the livers of four fish (*Notothenia neglecta*) about 3 years old. All these specimens, except for the fish, were taken on Signy Island, as far removed as possible from the Survey's base. The fish are the most abundant species in local waters and were taken in Borge Bay on the east side of the island. They are bottom feeders and are preyed on by shags and seals. The birds were killed by pithing or with a blunt instrument, except for the shags which were shot with a rifle. Dissecting instruments were washed in acetone which was also sampled as a precaution and later found to be completely free from pesticide residues. The items for analysis were placed in glass containers with caps lined with metal foil. These containers had been specially cleaned and prepared in this Laboratory. The samples were then maintained in a continuously frozen state during the journey to London where they were stored at  $-25^{\circ}\text{C}$  pending analysis.

The samples were all in an excellent state of preservation when examined and showed no signs of decomposition. They were extracted with hexane or an acetone-hexane mixture, and these extracts cleaned up by the method of de Faubert Maunier *et al.*<sup>10</sup> which includes a dimethylformamide-hexane partition followed by passage through a column of prepared alumina. The solutions which resulted were then examined by gas-liquid chromatography using silicone, Apiezon and cyanosilicone columns, with electron-capture detection<sup>11,12</sup>. The solutions were further examined by a thin-layer chromatographic method<sup>13,14</sup>, by which the solutions were spotted on to silica gel plates and developed with a 1 per cent solution of acetone in hexane. After development, the appropriate areas of the thin-layer, corresponding to concurrently developed standard solutions of pesticides, were removed and extracted with hexane. These extracts were examined by gas-liquid chromatography and the identity and proportions of each of the compounds detected by the initial examination confirmed. The presence of *pp'*-DDT in the samples was further confirmed qualitatively and quantitatively by warming the appropriate thin-layer extract with ethanolic sodium hydroxide. The *pp'*-DDE formed by hydrolysis of the *pp'*-DDT was then determined by gas-liquid chromatography as already described. The presence of *pp'*-TDE was confirmed in a

similar manner by hydrolysis to *pp'*-DEM (1-chloro-2,2-di-4-chlorophenylethylene).

The results of the analyses are set out in Table 1. They give clear indication that all the penguins examined contained small amounts of BHC isomers, dieldrin, *pp'*-DDT and *pp'*-DDE in their liver, blubber and fat. Most of these samples also contained small amounts of heptachlor epoxide and *pp'*-TDE. Not shown in the table, but also detected in some of the samples, were small amounts, generally less than 0.005 p.p.m., of *pp'*-DME, a further breakdown product of DDT and generally regarded as non-toxic. Most of the pesticide residues detected were of the order of 0.001-0.010 p.p.m. but some of the samples contained nearly 0.050 p.p.m. of *pp'*-DDE in the blubber and fat. There was no apparent relation between the age of the birds and the distribution of results. The three penguin eggs, each weighing about 100 g, also contained BHC isomers, dieldrin, *pp'*-DDT and *pp'*-DDE in similar proportions to those found in the birds.

The stomach contents of the birds consisted almost wholly of krill (*Euphausia* sp.). The Antarctic seas are very rich in krill which form the main food of these penguins. Analysis of these krill samples indicated that here at least was one source of the pesticides found in the birds. Precisely the same compounds, but in lower proportions, were detected in the krill as in the birds, except that heptachlor epoxide was not detected in the krill, probably because the concentrations were less than those capable of being detected, allowing for the size of the samples and the methods used.

All the fish livers showed BHC isomers, heptachlor epoxide, dieldrin, DDT and its metabolites, in small amounts similar to those found in the penguin livers.

The skua is known to nest in Antarctica and the specimens taken for this study came from nests on Signy Island. Outside the breeding season, the birds range widely and often appear in the tropics. They are scavengers and predators and such birds have often been shown to contain large amounts of pesticide residues<sup>17,18</sup>. Nevertheless, 0.73 p.p.m. of heptachlor epoxide, 26 p.p.m. of *pp'*-DDE and 2.5 p.p.m. of *pp'*-DDT are, by any standard, very high concentrations to find in the fat of a wild bird.

Blue-eyed shags nest in rookeries and are not wanderers. The specimens examined here were from a shag rookery on Signy Island and had probably never left the local waters. As might be expected, therefore, both the identity and proportion of the pesticides found in these birds are the same as those found in the penguins except that the *pp'*-DDE and *pp'*-DDT contents appear to be a little higher.

Shortly after receiving and analysing the samples described above, we also received the livers of three sheathbills (*Chionis alba*). These had been taken on a separate occasion by the British Antarctic Survey on Signy Island following the sudden deaths of a number of these birds from unknown causes. All these livers contained *pp'*-DDE (0.030, 0.100 and 0.014 p.p.m.) and two of them contained dieldrin (0.015 and 0.012 p.p.m.) but no other pesticide residues.

The picture revealed by this present investigation shows that all the wildlife sampled on Signy Island and in its surrounding waters was contaminated by the persistent organochlorine pesticides. The great majority of the samples contained small amounts of four of the most commonly used of these compounds or their toxic metabolites—BHC isomers, heptachlor epoxide (a very toxic metabolite of heptachlor), dieldrin, *pp'*-DDT, and two of its toxic metabolites, *pp'*-DDE and *pp'*-TDE. The pesticides themselves have now been in large scale agricultural and veterinary use for about 15–20 years. In this time, substantial amounts would have found their way down rivers to the oceans and have been carried away by deep sea currents. Large amounts would also have been lost to the atmosphere by volatilization and some of this would have returned to some other part of the land or sea by precipitation<sup>8</sup>. It is clear from the analysis of the krill in the stomachs of the penguins and of the fish livers that the Antarctic waters contain not only traces of DDT but also traces of other organochlorine pesticides. The analysis of the penguins and their eggs and of the blue-eyed shags shows that this contamination is also present in the avian wildlife of the region. It thus seems possible that the DDT found in the early studies may, in fact, have been the first signs that contamination had reached Antarctica through the media of the seas and air.

The penguins of Antarctica have the auk family (*Alcidae*) as their ecological equivalent in the northern hemisphere. Some measure of the degree of contamination of Antarctic waters might be gained from a comparison of the results from the present study and those from studies already made of the auk family. Around the shores of the United Kingdom this family is represented chiefly by razorbills (*Alca torda*), puffins (*Fratercula*

*arctica*), guillemots (*Uria aalge*) and black guillemots (*Cepphus grylle*). The pesticide residues occurring in the eggs of the first three of these species have been studied closely for the past 4 years so that the general concentrations of these compounds in their eggs are well established<sup>5,15,16</sup>. The concentrations are of the order of fifty times higher than were contained in the penguin eggs studied here which would suggest that the waters of Antarctica are still far less contaminated than those around the British Isles.

We thank the British Antarctic Survey for their co-operation in this enterprise and, in particular, Dr J. R. Brotherhood, of the Survey, who took all the samples and arranged their dispatch to England.

## The Alaska Earthquake of 1964

by

WALLACE R. HANSEN

US Geological Survey,  
Denver, Colorado

Now that the dust has settled it is possible to assess the long term effects of the Alaskan earthquake on March 27, both on the activities of man and on the wild life of the State.

THE greatest earthquake to strike North America in this century rocked southern Alaska on March 27, 1964, at 5.36 p.m. local time<sup>1</sup>. The generative area, however, was mostly uninhabited, and although the long period vibrations that reached distant inhabited areas (such as Anchorage) heavily damaged many large or tall buildings, they spared most of the small wood-frame buildings. Thus, despite its great size, this earthquake ranks far below many other natural disasters in terms of property damage and loss of life. Damage due to vibration was significant chiefly at Anchorage and Whittier. At Anchorage, all buildings of ten stories or more sustained moderate to heavy damage, four structures of four to nine stories collapsed or were damaged beyond repair, and several low buildings were totally destroyed<sup>11</sup>. But many small dwellings, stores and commercial buildings were hardly damaged, if at all. Nevertheless, thousands were left homeless.

The timing of the earthquake—during a school holiday and at a time when many people were returning from work—also contributed to the low casualty rate, which was 130 killed, 16 of whom died by drowning outside Alaska. In fact, drowning in sea waves caused more deaths than all other factors combined. The earthquake disrupted the economy of the entire State, and total property damage to Alaska exceeded 311 million dollars.

Earthquake damage to the cities, towns and villages of southern Alaska was caused by direct seismic vibration, ground breakage, mud or sand emission from cracks, ground lurching, subaerial and submarine landslides, fires, sea waves, and land-level changes (Table 1). Not all these factors caused damage in every community. Some communities were devastated by only one. The village of Chenega in Prince William Sound, for example, was destroyed by a sea wave.

Overall, landslides probably caused the most damage to man-made structures and property, but sea waves took the most lives. Many Alaska communities can be reached only by water or air, water transportation being the base of the State's fishing industry and one of her vital links with the outside world. Severe damage to port and harbour facilities, therefore, was a great blow to the economy. In addition, destruction of railroad terminal and port facilities at Seward and Whittier, coupled with destruction of the highway port of Valdez, deprived Alaska of any ice-free, all-weather ship terminals. The submarine sliding at Seward, Valdez and Whittier generated large local sea waves that completed the destruction of docks, piers, and small-boat harbours. At Valdez, more than forty boats were smashed. At Seward, tugs, fishing boats and a tanker were washed ashore, and burning petroleum swept into the bay by submarine sliding

Table 1. SUMMARY OF EARTHQUAKE DAMAGES TO ALASKAN COMMUNITIES

was carried back across the waterfront by the returning surge of water. At Kodiak, damage was caused mostly by a succession of huge seismic sea waves, compounded by tectonic subsidence of about 2 m.

### Geophysical Observations

The earthquake had a magnitude variously computed at 8.3–8.75 on the Richter scale. The epicentre of the main shock was near the north margin of Prince William Sound, about 130 km east-south-east of Anchorage at lat. 61.1° N., long. 147.7° W.<sup>2</sup> Its hypocentre was about 21 km deep. The thousands of aftershocks were dispersed chiefly along the continental margin of the Aleutian Trench between Prince William Sound and the Trinity Islands south of Kodiak. This area, about 100 km across and 700 km long, coincided with a zone of tectonic uplift and was the probable source of the seismic sea waves that washed the shores of the Pacific Ocean as far south as Antarctica<sup>3</sup>.

Ten aftershocks stronger than Richter magnitude 6 followed within 24 h of the first shock. Within a week seventy-five aftershocks with magnitudes greater than 4 had been recorded<sup>2</sup>, including one of magnitude 6.7 on March 29 (March 30, 02:18:05.6 G.M.T.). About 12,000 aftershocks with magnitudes equal to or greater than 3.5 probably occurred in the 69 days after the main shock<sup>4</sup>, and several thousand more were recorded in the next year and a half<sup>5</sup>.

The immediate effect of the earthquake was increased by the duration of strong ground motion. Although strong motion instruments were not at the time emplaced in the affected area, so that the duration of the motion had to be surmised from the best estimates of eye-witnesses, timings by wrist or pocket watch ranged from 1.5 to 7 min or more. Most estimates were grouped within the range of 3–4 min.

The main shock was felt throughout most of Alaska, including points as far as 1,200 km from the epicentre. It caused significant damage to ground and structures within an area of about 120,000 km<sup>2</sup> (ref. 6). Marked fluctuations were recorded in water wells as far away as Georgia, Florida and Puerto Rico<sup>7</sup>.

Although the earthquake was felt throughout Alaska, the intensity diminished appreciably northwards from mountainous southern Alaska to the intermontane plateau of the interior. Damage extended generally throughout an arcuate area within about 250 km of Prince William

Sound roughly coincidental with a zone of tectonic land-level change. In this zone, crustal deformation due to land-level change was more marked than any deformation known to be related to any previous earthquake<sup>8</sup>.

Probably 200,000 km<sup>2</sup>, possibly much more, an area larger perhaps than the British Isles, was tectonically elevated or depressed (Fig. 1). The line of maximum subsidence coincided with the mountain axis of the Kenai Peninsula and Kodiak Island, where downwarping exceeded 2 m. Uplift over wide areas of Prince William Sound averaged about 2 m, and in an area of surface rupture on Montague Island on the south side of the sound uplift locally reached 10 m (ref. 3); south-west from Montague Island the sea bottom was uplifted locally more than 15 m (ref. 9), and uplift of the sea bottom in the Gulf of Alaska generated the tsunamis that spread across the Pacific Ocean<sup>10</sup>. Triangulation by the Coast and Geodetic Survey also indicated large-scale lateral translations of the Prince William Sound area, probably accompanied by crustal extension. In general, Prince William Sound and the contiguous Chugach Mountains moved southward as much as 3 m relative to adjacent areas west and north. On the other hand, crustal shortening was greater than 3 m in a north-south direction between Montague Island and Latouche Island, which are only about 10 km apart. Landslides, sometimes submarine, caused spectacular damage in Anchorage, Seward and Valdez. Four large slides in built-up parts of Anchorage were caused by failures along bluff lines in soft clay the water content of which at critical depths exceeded its liquid limit. At Valdez and Seward, spontaneous liquefaction of granular deltaic materials initiated submarine slumping which carried away the waterfronts of both towns. The seaward slopes of the deltas, moreover, were less stable after the quake than before.

Probably few earthquakes have so strongly affected the fauna and flora of a region as that in Alaska. The total biological effects will not be known for a long time to come. Wholesale extermination of marine organisms followed crustal changes which have completely altered the ecologic setting of the shore. Broad expanses of shore and sea bottom were raised above tide water in Prince William Sound, and in the subsided areas of the Kenai Peninsula and Kodiak Island, which had previously provided winter forage for moose and nesting grounds for migratory birds, coastal marshlands and forest were inundated by salt water.

Sea waves caused enormous direct destruction of organisms. In addition, salt water invasion of many coastal lakes destroyed the freshwater habitat, at least temporarily. Many fish were destroyed when streams and lakes temporarily lost water into ground cracks, or when streams were dammed by landslides. Subsidence in some areas, however, opened new spawning habitats by inundating previously impassable falls and velocity barriers in coastal streams. Some spawning beds for salmon were destroyed by siltation on river deltas, and direct kills of eggs and fry were caused by disturbance of the gravel beds of streams<sup>14</sup>.

The salmon fishery is one of Alaska's foremost resources, and the full impact of the earthquake on this fishery will not be felt until the matured hatch of 1964 returns from the sea to spawn. Spawning areas for pink and chum salmon, which are intertidal spawners, received major damage in nearly all coastal sections affected by sea waves, uplift, or subsidence. On Kodiak and Afognak Islands, moreover, waves struck at a critical time when pink salmon fry were just moving from the spawning beds to the estuaries. Sport fisheries, including salmon, trout, char and smelt, were all damaged by environmental disturbances, especially in spawning areas.

Vast numbers of red snapper (red rock cod) were killed in Port Valdez, Port Wells, and in other parts of Prince William Sound, perhaps by turbulence or sudden upwelling associated with submarine slumping. Countless thousands of these fish—normally bottom dwellers—were left floating dead at the surface<sup>8,9</sup>. Dead dungeness crabs were found in the Copper River Delta area after the earthquake, but the commercial catch was not affected. Much of the commercial clam habitat in Prince William Sound and in the Copper River Delta was damaged or destroyed. There was a high mortality of razor clams, cockles and duck clams. Duck clams, moreover, are an important food for sea ducks, divers and other birds, as well as the starry flounder. Recovery of clams as a commercial resource is expected to be slow. Many of the new beach areas are unsuited for clam habitat. In suitable areas, moreover, reseeded clams will require 8–12 yr of growth before reaching commercial size<sup>14</sup>.

The effects of the earthquake on wildlife on land are mixed, and some short term effects have even been beneficial. Some mountain goats were said to have been killed by avalanches, as probably were some mountain sheep, deer and moose. Uplift favourably altered some nesting habitats of ducks, geese and trumpeter swans by

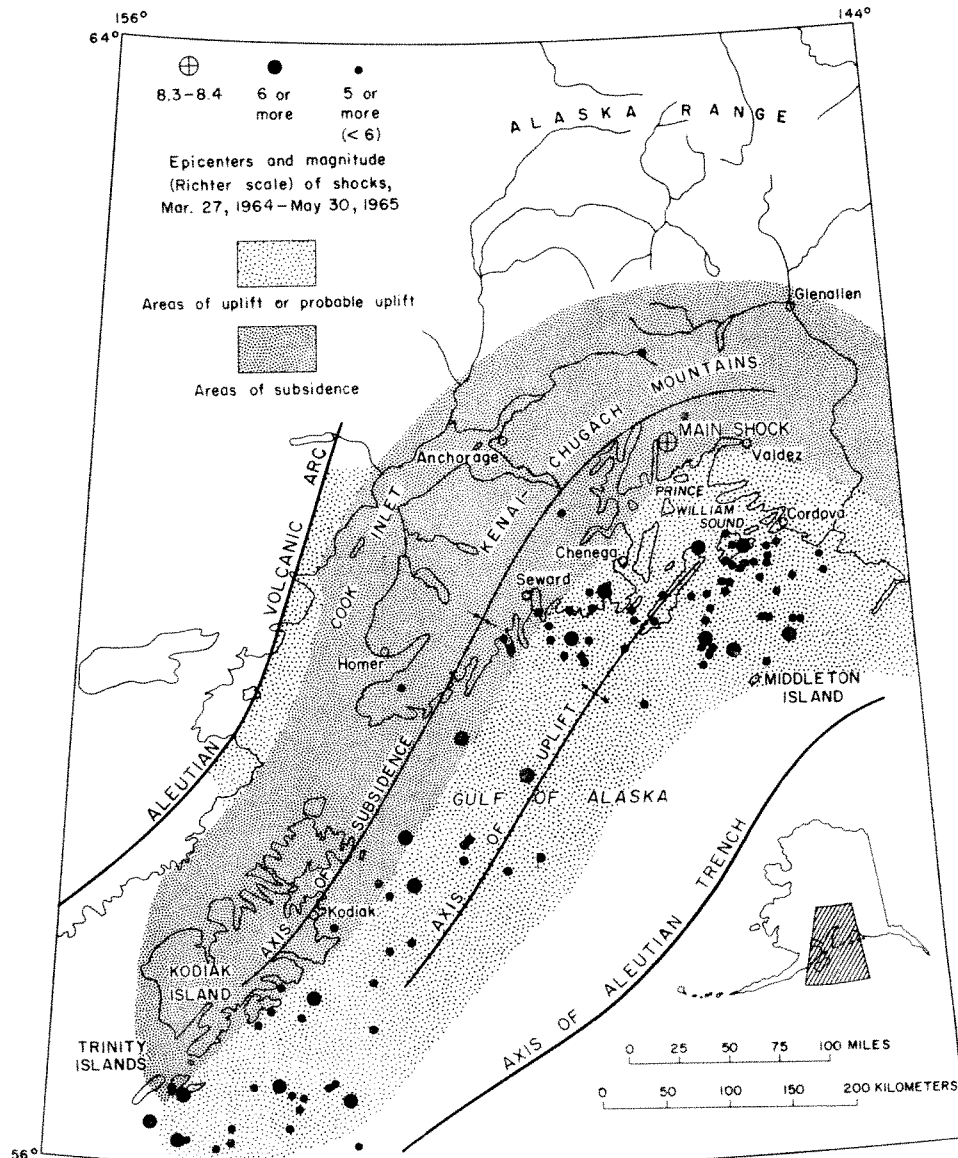

Fig. 1. Map of south central Alaska showing epicentre, major aftershocks, and areas of tectonic changes in land level accompanying the earthquake of March 27, 1964. Data chiefly from refs. 2, 3, 5, 6.

eliminating flood dangers, but the long term ecology may be less favourable—a new balance will be established as brush gradually invades upland areas and vegetation spreads over former mud flats; nesting places will shift accordingly (J. W. Brooks, personal communication). In tectonically subsided areas, where extensive freshwater marshlands and meadows were invaded by salt water, populations of moose will have to readjust downward to the new restricted food supply.

Secondary damage effects of the earthquake reached far beyond Alaska as seismic sea waves spread rapidly across the Pacific Ocean to Hawaii, Japan and Antarctica<sup>10</sup>. Van Dorn concluded that the waves were caused by the sudden displacement of water in the Gulf of Alaska accompanying the uplift of thousands of square kilometres of sea floor. A maximum wave height of more than a metre was reported from the Antarctic Peninsula (Palmer Peninsula) but heights in Japan were only 0.3 m or so. Hilo, Hawaii, had a 2 m wave, but only minor damage. Apparently the source was directional, the waves radiating preferentially south-eastward along the west coast of North America.

Atmospheric effects also reached far beyond Alaska. A pressure wave was recorded by microbarographs at Scripps Institute of Oceanography at La Jolla, California, more than 3,200 km from the epicentre, and also at the University of California at Berkeley<sup>10,17</sup>. This wave, which resembled pressure waves generated by nuclear explosions, travelled at acoustical velocity, reaching La Jolla 3 h 19 min after the onset of the quake. It was an atmospheric counterpart of the seismic sea waves generated at sea, and must also have been caused by the rapid tectonic uplift of the sea floor and the overlying water column<sup>3</sup>.

Atmospheric waves coupled to surface seismic waves were also recorded at Berkeley. These waves began at

Berkeley about 14 min after the onset of the quake and lasted about 4 h (ref. 17).

The earthquake also generated ordinary sound waves of very low sub-audible frequencies in the atmosphere<sup>18</sup>. These sound waves were radiated by the earthquake at the epicentre and by seismic waves passing through the Earth remote from the epicentre, exciting the atmosphere with their passage. Thus, the Rocky Mountains and the Mississippi Delta were local sources of sound as they vibrated with the passage of the shock. In addition Rayleigh waves crossing the continent displaced the ground surface about 5 cm in the conterminous United States and produced strong sub-audible sound waves; they then travelled vertically upward to the ionosphere, amplifying greatly as they ascended. The ionosphere, in turn, oscillated up and down at a rate of several hundred m/sec in motions that were detected by means of reflected radio waves broadcast from one ground station to another.

## Human Red Cell Peptidases

by

W. H. P. LEWIS  
HARRY HARRIS

MRC Human Biochemical Genetics Research Unit,  
Galton Laboratory,  
University College, London

A new method for characterizing peptidases in terms of electrophoretic behaviour in starch gel and of substrate specificity is described. A survey of red cells from a large number of people has revealed genetically determined variants of two of these enzymes. Separate loci appear to be involved.

PEPTIDASES with different specificities are known to occur in erythrocytes<sup>1-6</sup>. Our procedure for characterizing several of these enzymes depends on the detection of peptidase activity after electrophoresis by the following sequence of reactions

The free amino-acid liberated by peptide hydrolysis (reaction (1)) is subjected to oxidative deamination by L-amino-acid oxidase (reaction (2)). The complete reaction sequence results in the appearance of a dark brown zone (oxidized dianisidine) at the site of peptidase activity

(reaction (3)). In the present work we have mainly used rattlesnake (*Crotalus adamanteus*) venom as the source of L-amino-acid oxidase. This has been found to be particularly active with leucine, isoleucine, phenylalanine, tyrosine, methionine and tryptophan; weakly active with arginine, valine and histidine; and inactive with aspartic acid, asparagine, cysteine, glutamic acid, glutamine, glycine, alanine, serine, lysine, threonine and proline. Only peptides from which one or another of the amino-acids in the most active group may be released have so far been tested as substrates with this staining procedure.

The procedure adopted is as follows. Haemolysates prepared by mixing one volume of washed packed red cells with two volumes of water or by sonication are subjected to starch gel electrophoresis at pH 7.4 for 18 h at 5 V/cm (bridge buffer, 0.1 molar *tris*/maleate; gel buffer, 0.005 molar *tris*/maleate). The samples are inserted into the gel on filter paper (Whatman No. 3 MM). The gels are kept cold during the run by metal cooling

plates through which water at 8° C is circulated. The gels are sliced in the usual manner, and the reaction mixture is poured on to the cut surface of the gel. The reaction mixture is prepared immediately before use by mixing 25 ml. of 2 per cent aqueous agar at 55° C with a solution containing 25 ml. of 0.2 molar phosphate/hydrochloric acid buffer, pH 7.5, 20 mg of peptide, 5 mg of crude *Crotalus adamanteus* venom (Sigma), 10 mg of horseradish peroxidase POD II (Boehringer Corp., Ltd.), 5 mg of *o*-dianisidine hydrochloride and 0.5 ml. of 0.1 molar manganese chloride. The starch gel with its agar overlay is then incubated for 1 h at 37° C.

Using the twelve dipeptides and the four tripeptides listed in Table 1, it has been possible to distinguish five sorts of peptidase present in erythrocytes in terms of their electrophoretic properties and of substrate specificity. They will be referred to as peptidases *A*, *B*, *C*, *D* and *E*. The electrophoretic components seen in each of these are shown in Fig. 1, and their relative activities with the different substrates are indicated in Table 1. Certain peptides, for example Phe-Tyr and Phe-Leu, appear to be readily hydrolysed by several of these peptidases, so that when they are used as substrates a complex pattern of electrophoretic components is seen. With other peptides simpler patterns are observed because they are mainly hydrolysed by only one of the peptidases present. Thus activity against Val-Leu appears to be restricted to peptidase *A*, activity against Leu-Gly-Gly to peptidase *B*, and activity against Leu-Pro to peptidase *D*. Fig. 2 illustrates the electrophoretic patterns observed with the same haemolysate when different substrates are used.

Preliminary studies on extracts from a variety of tissues indicate that the peptidases found in the red cell are probably widely distributed. But other peptidases not seen in the red cells also occur, and their characterization by the methods described here is in progress.

Peptidase *A* hydrolyses all the dipeptides (except Leu-Pro) listed in Table 1, although the activity varies somewhat from substrate to substrate. No hydrolysis of any of the tripeptides has been observed. At least three electrophoretically distinct zones of activity can be regularly detected and all appear to show the same substrate specificity. The slowest of these zones is always very much more intense than the others and would appear to account for most of the activity of peptidase *A* present in red cells.

Peptidase *B* is very active against the tripeptide Leu-Gly-Gly and also the dipeptides Phe-Tyr and Phe-Leu. It shows weaker activity against the tripeptides Leu-Gly-Phe, Tyr-Tyr-Tyr and Leu-Leu-Leu and also against the dipeptides Pro-Phe and Lys-Leu. This enzyme is probably the same as the erythrocyte tripeptidase described by Adams, Davis and Smith<sup>4</sup>. If so the present findings indicate that this enzyme has a broader specificity than previously thought, because certain dipeptides are also hydrolysed quite readily. Depending on the total level of activity in the haemolysate and the substrate

Fig. 1. Diagram showing electrophoretic components in five different red cell peptidases.

used, four or more distinct electrophoretic components with peptidase *B* activity can be seen. The slowest is the most active and the others show diminishing activity with increasing electrophoretic mobility.

Peptidase *C* shows activity against a number of the dipeptides listed in Table 1, but not with the tripeptides. Its substrate specificity, however, is very different from that of peptidase *A* which also appears to be primarily a dipeptidase. Thus peptidase *C* shows much more activity against Lys-Leu than peptidase *A*, and also relatively more activity against Phe-Tyr. In contrast, Gly-Leu and Gly-Phe are much less readily hydrolysed by peptidase *C* than by peptidase *A*. In freshly prepared red cell sonicates most of the peptidase *C* activity is present in a single zone as indicated in Fig. 1. A weaker and more diffuse area of activity migrating more rapidly also occurs, however, and this is sometimes seen to be differentiated into two distinct zones. If the sonicate is kept for a few days at +4° C and then re-examined the main zone originally seen is weaker, but the faster zones are more intense. The changes seem to be progressive with time. As the slowest of the three zones diminishes in activity the middle and subsequently the fastest become more active. If mercaptoethanol is added to the older sonicates to give a concentration of 20 mmolar and they are incubated for 60 min at 37° C before electrophoresis, the pattern reverts to that originally observed with the fresh sample. On the other hand, if a fresh sonicate is preincubated with oxidized glutathione (25 mmolar, 60 min at 37° C), a pattern similar to that seen in the older samples is obtained, and the fastest of the three zones is the most intense. These findings suggest that the electrophoretic changes with ageing of the sample may possibly be explained in terms of reactions between free -SH groups on the enzyme molecule and oxidized glutathione present in the red cell sonicate. The formation of a disulphide bridge linking a half molecule of oxidized glutathione to the enzyme would increase the net negative charge by 1 unit for each -SH group engaging in this reaction. It is noteworthy that similar changes are not seen in the electrophoretic patterns of peptidases *A* or *B* in the older sonicates, nor are these patterns modified by preincubation with oxidized glutathione.

Peptidase *D* has so far only been found to show significant activity with Leu-Pro. It probably therefore,

Fig. 2. Peptidase patterns seen after starch gel electrophoresis of a single haemolysate and development with six different substrates. (1) Leu-Pro; (2) Pro-Phe; (3) Phe-Tyr; (4) Leu-Gly-Gly; (5) Leu-Gly; (6) Lys-Leu.

corresponds to the enzyme "prolidase" described by Adams, McFadden and Smith<sup>2</sup>. As indicated in Fig. 1, there is one main zone of activity with a weaker and more diffuse zone moving ahead. Changes in the electrophoretic pattern occur in red cell sonicates which have been kept for a few days at 4° C and resemble those seen with peptidase C. The patterns can be modified in a similar way by treatment with mercaptoethanol, and apparently can be induced in fresh sonicates by incubation with oxidized glutathione.

Peptidase E has been detected with Leu-Leu, Lys-Leu, Phe-Leu and Phe-Tyr, but its activity in each case is relatively weak. Older sonicates show electrophoretic changes resembling those seen with peptidase C and D, and analogous changes are also brought about by treatment with mercaptoethanol and oxidized glutathione. It is interesting that peptidase E appears to be the only red cell peptidase which shows significant hydrolysis of leucyl-β-naphthylamide. This substrate has been widely used both histochemically and after electrophoresis for the detection of what has been referred to as "peptidase" or "naphthylamidase" activity in various tissues.

The electrophoretic patterns shown in Figs. 1 and 2 are those most commonly seen. During quite extensive population and family studies, however, several genetically determined variants of peptidase A and of peptidase B have been identified. A systematic search for variants of peptidase C, D or E, however, has not yet been carried out. The variants of peptidase A and B have been found to be independent of each other and are not associated with any variation of the pattern of peptidases C, D or E, thus confirming the conclusion based on the substrate specificity investigations that several quite different peptidases are demonstrable in these conditions.

We will refer to the usual form of peptidase A as Pep A 1 and the variant types so far identified as Pep A 2-1, Pep A 2, Pep A 3-1 and Pep A 4-1. Similarly the usual form of peptidase B will be called Pep B 1 and the variant types Pep B 2-1, Pep B 3-1 and Pep B 4-1. The frequencies with which these different types have been observed in a survey of more than 2,000 unrelated people of European origin and in more than 500 people of African origin are

Table 2. INCIDENCE OF PEPTIDASE PHENOTYPES IN DIFFERENT POPULATION SAMPLES

	Europeans	Resident in UK	Negroes Yoruba (Nigeria)	Bantu (S. Africa)
Peptidase A 1	2,279	254	127	87
2-1	—	36	25	11
2	—	3	3	2
3-1	1	1	—	—
4-1	3	—	—	—
Total tested	2,283	294	155	100
Peptidase B 1	2,188	294	155	100
2-1	6	—	—	—
3-1	2	—	—	—
4-1	1	—	—	—
Total tested	2,197	294	155	100

given in Table 2. The Negroes which were investigated were from three different population groups; 155 were Yoruba from Nigeria, 100 were Bantu from South Africa and 294 were Negroes of various origins resident in England, largely recent immigrants from the West Indies. Pep A 2-1 has not been seen in the European population, but it is relatively common in Negroes, occurring in 11 per cent to 16 per cent of people in the three population groups examined. Similarly Pep A 2 is absent in the European sample, but has an appreciable frequency among the Negroes (0.5 per cent to 2 per cent). Pep A 3-1 has been found once in the unrelated European sample and once among the Negroes. Peptidase A 4-1 is also relatively rare. Three examples were observed among the Europeans and none among the Negroes. Of the peptidase B variants, Pep B 2-1 is the commonest and appears to occur in about one in 350 Europeans. It has not been seen in the Negro groups. In a series of 104 "Cape Malay" individuals (not listed in Table 2) from South Africa, however, two examples of Pep B 2-1 were observed. It is thus possible that this type may have a relatively higher incidence among people of oriental origin.

Pep A 2-1 and Pep A 2 have the electrophoretic patterns shown in Fig. 3. Segregation data in a series of families in which at least one parent was either Pep A 2-1 or Pep A 2 are given in Table 3. These data, as well as the segregation patterns observed in several pedigrees

Fig. 3. I, Electrophoretic patterns of five different peptidase A phenotypes. Development with Leu-Gly as substrate. II, Diagram of the principal and minor bands in the same five phenotypes.

Table 3. SEGREGATION OF PEPTIDASE A PHENOTYPES IN THIRTY MATINGS IN WHICH AT LEAST ONE PARENT IS PEP A 2-1 OR PEP A 2

Parents	No. of matings	Children			Totals
		Pep A 1	Pep A 2-1	Pep A 2	
1 × 2-1	26	25	34 (7)	—	59
2-1 × 2-1	3	1	2 (1)	1	4
1 × 2	1	—	2 (1)	—	2
Totals	30	26	38 (9)	1	65

Figures in parentheses indicate the number of families selected through a child who was Pep A 2-1. In the other families the propositus was a parent who was Pep A 2-1.

involving three generations, is consistent with the simple hypothesis that Pep A 2-1 individuals are heterozygous for an autosomal allele which in homozygotes produces type Pep A 2.

The presumed heterozygote Pep A 2-1 shows three main components, two of which correspond in mobilities to the main components of the presumed homozygotes Pep A 1 and Pep A 2, while the third has an exactly intermediate mobility. This characteristic triple-banded pattern in heterozygotes is seen in a number of other enzymes and is usually thought to arise in situations where the enzyme in the homozygote contains two identical polypeptide chains or sub-units, whose primary structure is determined by a single allele. In the present case we suppose that the common allele determines a polypeptide  $\alpha^1$ , and that the allele which in homozygotes gives Pep A 2 determines a polypeptide  $\alpha^2$  which differs in structure from  $\alpha^1$  possibly by a single amino-acid substitution. If so, the main enzyme component in Pep A 1 would have the structure  $\alpha^1\alpha^1$ , the main component in Pep A 2 would have the structure  $\alpha^2\alpha^2$ , and the three main components seen in Pep A 2-1 would have the structures  $\alpha^1\alpha^1$ ,  $\alpha^1\alpha^2$  and  $\alpha^2\alpha^2$ .

Pep A 3-1 and Pep A 4-1 (Fig. 3), like Pep A 2-1, each show two new components as well as a component with the same mobility as the principal component in Pep A 1. In both these types, however, the new components migrate more slowly than the Pep A 1 component. In an investigation of the families of two individuals with Pep A 3-1, seven further examples of this phenotype were found. In the case of the individuals with Pep A 4-1 six further examples of the same phenotype were found among the immediate relatives. The pedigrees indicate that these phenotypes occur in individuals who are heterozygotes. If the sub-unit hypothesis of peptidase A outlined earlier is correct, then it is likely that types Pep A 3-1 and Pep A 4-1 are heterozygous for rare alleles which determine variant sub-units which may be designated  $\alpha^3$  and  $\alpha^4$  respectively. If so, the three components seen in Pep A 3-1 will be expected to have the structures  $\alpha^1\alpha^1$ ,  $\alpha^1\alpha^3$  and  $\alpha^3\alpha^3$ ; and the three components in Pep A 4-1, the structures  $\alpha^1\alpha^1$ ,  $\alpha^1\alpha^4$  and  $\alpha^4\alpha^4$ . The slowest bands in both Pep A 3-1 and Pep A 4-1 are somewhat weaker than the others. This could arise if sub-units  $\alpha^3$  and  $\alpha^4$  were catalytically less efficient than  $\alpha^1$ , or if they were present in smaller amounts because they were less stable or were synthesized at a slower rate than  $\alpha^1$ .

Minor components similar to those seen ahead of the main component in Pep A 1 may also be seen ahead of the main component in Pep A 2 and of its homologue in Pep A 2-1. They are also seen ahead of the fast principal component in Pep A 3-1 and Pep A 4-1. It is possible that similar minor components may also occur in association with the other principal components present in Pep A 2-1, Pep A 3-1 and Pep A 4-1 but are obscured by the more intense components in the patterns.

The pattern of components in the phenotype Pep B 2-1 is shown in Fig. 4. There is a series of zones with mobilities similar to those in Pep B 1, but there is also an extra slower moving zone. Among the offspring of eleven matings where one parent was Pep B 1 and the other Pep B 2-1, sixteen children were found to be Pep B 1 and sixteen Pep B 2-1 (excluding propositi). These findings, as well as the overall segregation pattern in the

pedigrees, indicate that the type occurs in individuals heterozygous for a rare autosomal gene.

The electrophoretic patterns observed in Pep B 2-1 can be explained most simply by supposing that the rare allele for which these individuals appear to be heterozygous alters the mobility of each of the series of Pep B isoenzymes in a regular manner. The effect of this allele would be to slow each of the isoenzymes by an amount equivalent to the normal difference in mobility between any consecutive pair of them. In an autosomal heterozygote the products of both alleles can be expected to be equally represented. Thus the pattern in Pep B 2-1 would be made up of the series of isoenzymes present in Pep B 1 and the series determined by the rare allele. These series are presumed to overlap, and so the distinctive feature of the Pep B 2-1 pattern would be the appearance of an extra slow component.

In the phenotype Pep B 3-1 (Fig. 4) the zones seen match those of Pep B 1 in electrophoretic mobility, but their relative intensities are different. The slowest is relatively weaker while each of the faster ones is relatively more intense than the corresponding zone in Pep B 1. Thus while in Pep B 1 the slowest zone is the most intense of the series, in Pep B 3-1 the next zone is the most intense. Two families in which the propositus was of type Pep B 3-1 have been investigated and four further examples of this type were found. The pedigrees suggest that individuals with this unusual phenotype are also heterozygous for a rare allele.

We can account for the electrophoretic pattern seen in Pep B 3-1 by supposing that the rare allele concerned causes an increase in the mobility of each of the usual series of components seen in Pep B 1 by an amount equivalent to the difference in mobility between any pair of them. The pattern in Pep B 3-1 would represent a mixture of the usual series of components determined by the common allele and the more rapidly moving series of components determined by the rare allele. In the usual series the slowest component is the most active, and this would presumably also be the case in the new series. The net effect in the mixture would be for the slowest zone to have approximately half the activity it has in Pep B 1, but the next zone, which represents a mixture of the second component in Pep B 1 and the slowest component in the new isoenzyme series, would be distinctly more intense.

Fig. 4. Diagram of electrophoretic patterns of four different peptidase B phenotypes. Development with Leu-Gly-Gly as substrate.

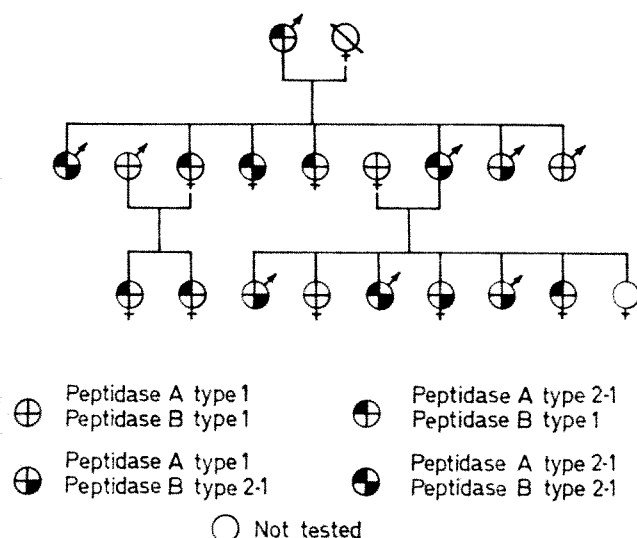

Fig. 5. Pedigree of a family in which peptidase A 2-1 and peptidase B 2-1 are segregating.

Similarly, each of the faster zones would appear to be relatively more intense than the zones with the same mobilities in Pep B 1.

In the phenotype Pep B 4-1 (Fig. 4) each of the components characteristic of Pep B 1, showing about half their usual activity, are seen and in addition there is a new series of components each of which has a greater mobility than the apparently corresponding component in Pep B 1. The investigation of the family gave results

consistent with the view that individuals showing this phenotype are heterozygous. We suppose that the rare allele involved determines the new series of components seen, and that the common allele present determines the usual series of peptidase B components which occur in this phenotype.

In one of the families investigated both the phenotypes Pep A 2-1 and Pep B 2-1 occurred. The pedigree is shown in Fig. 5. There is one mating between an individual who has the phenotype Pep A 2-1/Pep B 2-1 and an individual who is Pep A 1/Pep B 1. Among the six children tested one is Pep A 1/Pep B 1, one is Pep A 2-1/Pep B 1, three are Pep A 1/Pep B 2-1, and one is Pep A 2-1/Pep B 2-1. Each of the four possible combinations occurs, and so recombination must have taken place. We conclude that the loci determining peptidase A and peptidase B are not closely linked. They are either well separated on the same chromosome or on different chromosomes.

We thank Dr H. Gordon, University of Cape Town, Dr N. C. Allan, University College Hospital, Ibadan, Dr T. E. Cleghorn and J. Harris, North London Blood Transfusion Service, and Drs J. H. Edwards and G. Chance, Institute of Child Health, University of Birmingham, for blood samples. Peptides were obtained from Miles-Yeda, Ltd., P.O. Box 26, Rehovoth, Israel, and Cyclo Chemical Co., Los Angeles I, California.

## Non-randomness of Amino-acid Changes in the Evolution of Homologous Proteins

by  
CHARLES J. EPSTEIN

Laboratory of Chemical Biology,  
National Institute of Arthritis  
and Metabolic Diseases,  
National Institutes of Health,  
Bethesda, Maryland

A calculation of the extent of the differences between homologous proteins shows that the amino-acid "mutations" are not as random as might have been thought. In fact, natural selection seems to act to favour those amino-acid substitutions that tend to maintain the original conformation of the protein.

Two principal methods have been used to assess the degree to which homologous proteins are related. One relies on estimating the number of amino-acids in the sequences that are identical<sup>1</sup>, and the second involves the determination of the smallest number of mutations necessary to convert one sequence into another<sup>2-4</sup>. Unfortunately, neither method provides information about the nature of the differences in the sequences or about the forces that have influenced these differences. To approach these questions, amino-acid exchanges (otherwise referred to as substitutions, replacements, or "mutations") have been analysed with regard to the degree to which the properties of the residue side-chains have altered<sup>5,6</sup>. In a previous study, exchanges were divided into three groups on the basis of the polarities of the amino-acids<sup>6</sup>. Group I exchanges were those in which polarity was not altered; group II exchanges were between polar amino-acids and glycine or alanine; and group III exchanges involved an alteration in polarity. The reasons for these assignments have been discussed pre-

viously<sup>6,7</sup> but will be briefly re-stated here. Experimental and theoretical considerations indicate that the polarity of a residue is very important in determining its effect on protein conformation. The interiors of globular proteins consist primarily of hydrophobic residues, while polar (or hydrophilic) residues are found on the surface and are accessible to the solvent. Glycine and alanine residues can be found in either place<sup>8</sup>. All other considerations apart, therefore, type I exchanges would be expected to produce much smaller alterations of protein conformation than would type III exchanges; the effects of type II exchanges would be large or small depending on the actual localization of the residues in the molecule. It was predicted therefore that analysis of amino-acid exchanges between homologous proteins with similar conformations would reveal principally type I exchanges and that type III exchanges would be few<sup>6</sup>. This was, in fact, found, and the results further suggested that the differences in sequence were less random than could be attributed to simple mutations even if the organization

Table 3. COMPARISON OF HOMOLOGOUS AND NON-HOMOLOGOUS AMINO-ACID SEQUENCES

Proteins (refs.)	Total	Residues different	$\Delta p$	All exchanges		Interior exchanges		'Surface' exchanges	
				$\Delta m$	Base changes	$\Delta m$	Base changes	$\Delta m$	Base changes
<b>Homologous</b>									
Haemoglobin: human $\beta$ and $\gamma$ chains (17, 18)	146	37	0.07	0.29	1.27	0.11	1.13	0.34	1.31

<b>Non-homologous</b>									
Myoglobin and hen egg lysozyme (9, 25)	129	124	0.50	0.52	1.64				
Ribonuclease (bovine) and lysozyme (23, 25)	124	118	0.45	0.47	1.56				

be determined<sup>2</sup>, all indices were calculated using the coefficients  $\Delta_{AB}$ . Because a significant number of residues in the homologous sequences are identical,  $\Delta p$  is always less than  $\Delta m$ . Both sets of values, but particularly the latter, are considerably less than the values observed with the non-homologous proteins (Table 3) and the calculated random values of 0.49 (for  $\Delta p_{\text{expected}}$ ) and 0.52 (for  $\Delta m_{\text{expected}}$ ). Except for the comparison of myoglobin and the haemoglobin  $\beta$ -chain, all values of  $\Delta m$  were 0.36 or less. Furthermore, the actual distribu-

tions of the coefficients of the individual amino-acid exchanges show a higher proportion of low values than do the distributions of the exchanges between non-homologous proteins (Fig. 1). The paucity of values of  $\Delta_{AB}$  greater than 0.75 is particularly striking in the subtilisin (BPN' and Carlsberg), ribonuclease (bovine and rat), and the various haemoglobin comparisons.

Because a knowledge of the types of amino-acid interchanges found among the chains of haemoglobin and myoglobin<sup>8</sup> has influenced the assumptions underlying the derivation of the coefficients of difference, it would be expected that the values of  $\Delta m$  and the distributions of  $\Delta_{AB}$  for the haemoglobin comparisons should be non-random, and this is what was found. On the other hand, the finding of non-randomness for the other comparisons indicates that the rules for haemoglobin are not unique and are applicable to other groups of proteins. We can therefore be more confident in accepting the non-random values for  $\Delta m$  as indicating the correctness of the hypothesis that the preservation of the "conformational" attributes of amino-acids in a protein sequence is important in the evolution of homologous proteins.

It has repeatedly been pointed out that the amino-acid or genetic code is non-random in its organization and that single base changes will often result in the substitution, if not of the same amino-acid, of a similar or related amino-acid<sup>7,11,14,15</sup>. This is readily apparent from an examination of the code<sup>15</sup> as depicted in Fig. 2. To obtain an estimate of the degree to which the structure of the code influences the nature of the substitutions, the coefficients of difference for all the amino-acid substitutions resulting from single base changes have been averaged for each codon, and the values for all codons for the same amino-acid have then been averaged. The resulting values (defined as  $\Delta_A$ ) which represent the expected coefficients of difference for random single base changes in amino-acid codons (the specific codon not being known) are shown in Table 4. These coefficients have been expressed in two ways: as coefficients for all possible mutations and as coefficients for observable mutations. The former values provide a quantitative estimate of the "conservative" nature of the amino-acid code and indicate the degree of non-randomness that the amino-acid code imposes on the results of random single-base mutations. Because comparisons of homologous amino-acid sequences cannot detect "isosemantic" mutations—mutations which do not result in a change of amino-acid—the  $\Delta_A$  for observable mutations must be used for comparative purposes. Its values range from 0.19 to 0.58, with a mean of 0.42 over all codons and of 0.38–0.39 if averaged over the compositions of haemoglobin (human  $\beta$ -chain) or ribonuclease (bovine). The latter thus represent the expected values for  $\Delta m$  if only single base changes can occur. It has been conjectured that transitions (mutations which substitute one pyrimidine for another or one purine for another) may occur more frequently than transversions<sup>16</sup> and may be more "conservative" in nature<sup>14</sup>, and values for  $\Delta_A$  and for expected  $\Delta m$  have therefore been calculated.

Fig. 1. Distributions of coefficients of difference for amino-acid exchanges between homologous proteins. For reference, distributions for comparisons of non-homologous proteins and for observable substitutions produced by randomly occurring single base changes are also shown.

Fig. 2. Organization of the amino-acid code<sup>15</sup> represented as a three-dimensional matrix to emphasize the relationships among the codons of the various amino-acids. The numbers, 1, 2, and 3, refer to the position of the base in the codon. The close spacings of the planes for U and C and for A and G in the third position indicate that, unless otherwise marked, the codons are degenerate for pyrimidine or purine bases in this position.

assuming each codon can undergo six (rather than three) transitions for each six transversions<sup>7</sup>. The expected  $\Delta m$ s fall slightly to about 0.37 (Table 4).

Calculations have also been carried out for double mutations in which a single codon is subjected to two successive base changes at either the same or in different positions. The values for  $\Delta_A$  (Table 4) are greater than were obtained for single base changes, although still not

as great as for random substitutions. If double base changes are examined from the point of view of how many base changes appear to be necessary in each codon, rather than how many actually were necessary, the number is considerably less than 2.0 and ranges from 1.17 to 1.52 (Table 4); the mean is 1.30. In other words, if each codon in a sequence were subjected to two successive but independent mutations, the resulting amino-acid sequence would appear to differ from the original one by only 1.3 mutations in each codon. If amino-acids are paired at random, the value for the apparent number of base substitutions is in the range 1.45–1.61 (ref. 2).

With the results presented here, it is possible to consider the following question. Are observed amino-acid substitutions non-random merely because they are of the type favoured by the organization of the amino-acid code, or are they even less random than the code would ensure? As was already noted, a series of one-base changes with transitions twice as frequent as would be expected for purely random mutations gives an expected  $\Delta m$  of 0.37. How different is this value from those for observed  $\Delta m$  (Table 3) which range from 0.28 to 0.40? Unfortunately, the two numbers are not directly comparable because observed amino-acid substitutions cannot be explained solely on the basis of single base changes within codons. In fact, the minimal number of base changes that must be postulated is of the order of 1.20–1.50 per substitution (Table 3). An estimate of the value of expected  $\Delta m$  for a series of random mutations giving a similar apparent number of base changes for each amino-acid substitution is therefore required as a standard of reference. Such a value has already been obtained for the random two-base changes: an expected  $\Delta m$  of 0.45 with 1.30 apparent base changes for each substitution. To facilitate the comparison of the observed values of  $\Delta m$  with random expectations, the appropriate results have been displayed graphic-

Table 4. PREDICTED COEFFICIENTS OF DIFFERENCE ( $\Delta_A$ )

Amino-acid	One-base changes					Two-base changes

ally in Fig. 3. When arranged in this form, all the observed exchanges lie considerably below the line representing codon-determined random substitutions, and the organization of the amino-acid code, conservative as it is, is not sufficient to explain the "conformational" non-randomness of amino-acid substitutions. It is inferred therefore that natural selection has operated to reduce the amount of variability in amino-acid residues to less than that which would result from a series of random mutations.

Within the limits imposed by the numerical system that has been used in these calculations selective forces do not appear to have eliminated all substitutions with large coefficients of difference. Otherwise it would be expected that the observed values of  $\Delta m$  would be closer to 0.1–0.2 than to 0.3. Part of the explanation for this situation may lie in the initial assumptions and in the arbitrary assignments of values to certain amino-acid substitutions. This is at present unavoidable. Another factor may be that when at least 25 per cent of the residues remain unchanged all amino-acids in a sequence are not subject to the same intensity of selection. Thus as has been

pointed out by Perutz *et al.*<sup>8</sup>, the residues on the surface of globin may be more variable with respect to polarity than those in the interior. To determine whether this could affect the values observed for  $\Delta m$ , the residues listed by Perutz *et al.*<sup>8</sup> as interior residues (based primarily on the analysis of the structure of myoglobin) were removed from consideration, and  $\Delta m$  was calculated separately for the interior residues and the surface residues of the  $\alpha$  and  $\beta$  and the  $\beta$  and  $\gamma$  chains of haemoglobin, and of the  $\beta$ -chain of haemoglobin and myoglobin (Table 3, Fig. 3). In all cases,  $\Delta m$  for the interior residues was less than 0.2, indicating that selection is indeed more rigorous for the interior. In the first two cases,  $\Delta m$  for the surface residues became slightly but not significantly higher, but for the myoglobin- $\beta$ -chain it rose to a value not very different from that corresponding to the random arrangement. In the latter instance it must be concluded that either selection of the type envisioned is not operating on the surface residues or that the discrepancy is in some way connected with the fact that myoglobin does not form tetramers while the  $\beta$ -chain of haemoglobin does. To test the latter possibility, all  $\beta$ -chain residues implicated in the formation of inter sub-unit contacts<sup>9</sup> were removed and  $\Delta m$  recalculated. This results in a fall of  $\Delta m$  from 0.45 to 0.43, the  $\Delta m$  of the group of inter-sub-unit contact residues being 0.58. The new value of  $\Delta m$  for the surface residues, while lower than before, is still too close to random to allow the absence of tetramerization to be invoked as the sole explanation for its relatively high value.

To sum up, a series of numerical values have been derived to express the conformational differences between amino-acids. These values, or coefficients of difference, have been used to calculate indices of difference for amino-acid exchanges between homologous proteins. All comparisons give indices of difference considerably lower than could be accounted for by random mutations, even if the organization of the amino-acid code is taken into account. We infer therefore that natural selection has acted in the evolution of homologous proteins to favour amino-acid substitutions that would be compatible with the retention of the original conformation of the protein, and conversely to eliminate those that would not.

# Characterization of Macromolecules by Constant Velocity Sedimentation

by

HANS NOLL

Department of Biological Sciences,  
Northwestern University, Evanston, Illinois

To exploit the analytical power of zone velocity centrifugation, a novel method has been developed using sucrose gradients calculated to give constant particle velocity.

ZONE velocity centrifugation is an indispensable tool for the fractionation and characterization of macromolecules<sup>1,2</sup> (ref. 1 has a collection of articles on this subject), but in practice the analytical power of the method has rarely been exploited either with respect to resolution or quantitative determination of the rates of sedimentation. Determination of sedimentation constants in sucrose gradients is complicated because, with the gradients and rotors normally used, the molecules slow down as they move away from the top layer, for the viscous drag of the medium increases more rapidly than the centrifugal force. The viscosity and density of the medium change in a complicated fashion along the sedimentation path, and so the mathematical computation of sedimentation coefficients<sup>3,4</sup> becomes too cumbersome for routine analyses. This difficulty can be overcome in part by the use of tables prepared by a computer programme<sup>5</sup>. Without standardization of the gradients, however, this is not practical, because each type of rotor, gradient and particle density requires a different set of solutions. For the special case of protein molecules of a certain density range Martin and Ames showed that a particular rotor combined with a specific gradient produced nearly constant sedimentation rates<sup>4</sup>. The sedimentation coefficient of the unknown components could then be determined from the ratio of mobilities relative to an internal standard. Application of this linear extrapolation to different gradients, rotors and particles is normally not justified and would lead to grossly erroneous *S* values. A general method that gives fairly accurate values and is applicable to all particles of equal density and osmotic behaviour, and to any given rotor type and gradient, makes use of an experimentally determined, usually non-linear calibration curve<sup>6-8</sup>. Although this method requires a valid internal standard of known sedimentation coefficient, it is simpler and more rapid than mathematical integration by computer. Furthermore, unlike the mathematical methods, it is not dependent on the validity of whatever assumptions are made about the hydrodynamic behaviour of the molecules which are being investigated.

In addition to causing these analytical and computational difficulties, the decrease in rates of sedimentation observed in the commonly used gradients also seriously limits the resolving power of the method, for the particles tend to pile up towards the bottom of the tube. In most gradients the separation between two components fails to improve with sedimentation beyond a third to a half of the entire length of the tube. Thus the potential resolution offered by the available length of path remains largely unexploited.

A very different approach expected to eliminate most of these difficulties and shortcomings would be the use of gradients that are specially designed to keep the sedimentation rate of particles of a given density constant throughout the length of the tube. This would be accomplished by constructing gradients in which the linear increase in the driving force acting on a particle with increasing distance from the centre of the rotor is exactly compensated by an equivalent increase in the opposing forces of viscous drag and buoyancy.

In this communication I derive the theory of constant velocity sedimentation in sucrose gradients and document its validity by experimental measurements with ribosomes and RNA. An extremely simple method for preparing isokinetic gradients will be described which makes it possible to determine sedimentation coefficients in the preparative ultracentrifuge with ease, speed and accuracy.

To derive the shape of the isokinetic sucrose gradient, I use the same basic equations used before<sup>3-5</sup> to describe the sedimentation behaviour of particles in arbitrary sucrose gradients. These equations have been derived with some restrictive assumptions: the particles should be (a) spherical and (b) unaffected by changes in the suspending medium with respect to shape and density. The first condition, derived from Stoke's law for spherical particles, implies that the frictional resistance is proportional to the viscosity of the medium. This condition is probably not very stringent, for non-spherical particles would not be expected to deviate much from this relationship. The second condition could be more critical; while it is certainly not fulfilled by osmotic particles, it is difficult to predict to what extent changing sucrose concentrations might influence the overall shape of various non-osmotic macromolecules. By comparison with spherical latex particles which are unaffected by the medium, however, this question can be put to a rigorous test.

At a given temperature, the rate at which a particle of density  $D_p$  sediments through a medium of density  $D_m$  and viscosity  $\eta_m$  in a centrifugation field  $\omega^2 r$  is

$$dr/dt = S_{20,w}(\omega^2/A)r(D_p - D_m)/\eta_m \quad (1)$$

The term  $A = (D_p - D_{20,w})/\eta_{20,w}$  has been introduced to normalize measurements with respect to temperature and viscosity of water at 20° C; it is constant for any given value of  $D_p$ . In a sucrose gradient both  $\eta_m$  and  $D_m$  are functions of the concentration of the sucrose and thus of the distance  $r$  of the medium from the centre of the rotor; within the concentration range being considered, they are approximated by the expressions<sup>9,10</sup>

$$\eta_m(r) = \exp\left(\alpha \frac{C}{100 - C} + \beta C^2 + \gamma\right) \quad (2)$$

in which  $\alpha$  and  $\beta$  are temperature dependent constants,  $C$  the sucrose concentration in per cent (w/v) and  $\gamma$  the natural logarithm of the viscosity of water at  $T^\circ\text{C}$ ; and

$$D_m(r) = \mu(C - C_t) + D_t \quad (3)$$

where  $\mu$  is a constant.

The initial conditions are defined by the distance  $r_t$  of the meniscus from the centre of rotation, by the choice of the sucrose concentration  $C_t$  at the top of the gradient and the corresponding values of  $D_t$ ,  $\eta_t$ .

If we now demand that the particles move at constant velocity, the second term in equation (1) must remain constant with increasing  $r$ , that is, as the particles increase their distance from the top layer

$$dr/dt = r(D_p - D_m)/\eta_m = \text{constant}$$

or

$$\eta_m(r)/\eta_t = r(D_p - D_m(r))/r_t(D_p - D_t) \quad (4)$$

Inserting into (4) the viscosity and density functions (2) and (3) we obtain the desired constant velocity sedimentation gradient

$$\exp\left(\alpha \frac{C}{100 - C} + \beta C^2 + \gamma\right) = m r [D_p - \mu(C - C_t) - D_t] \quad (5)$$

in which

$$m = \eta_t/r_t(D_p - D_t)$$

Fig. 1. Shape of the isokinetic gradient. Solid line represents theoretical curve, broken line indicates approximation with mixing device in Fig. 2. To find the parameters ( $V_m$ ,  $C_R$ ) giving satisfactory approximation, three points were selected on the theoretical curve corresponding to the top concentration  $C_t$ , an intermediate concentration  $C_i$  and the bottom concentration  $C_b$ . The values of  $V_m$  and  $C_R$  of that curve of equation (6) which is fixed by these three points were then found. This produced the transcendental equation

$$(C_v - C_t) e^{-V/V_m} (1 - e^{-V/V_m})^{-1} = (C_b - C_t) e^{-V_b/V_m} (1 - e^{-V_b/V_m})^{-1}$$

which is solved for  $V_m$  by graphical methods or computer approximation.

$\triangle$  ---  $\triangle$ ,  $C_v = C_R - (C_R - C_t) e^{-V/V_m}$ ;  $\circ$  ---  $\circ$ ,  $C = f(r)$  from equation (5).

Fig. 2. Preparation of the isokinetic gradients. Convex exponential gradients according to equation (6) are conveniently prepared with a burette and mixing chamber<sup>11</sup>. The burette contains a sucrose solution of a concentration  $C_R$  and is connected through an air-tight rubber stopper to a mixing flask with magnetic stirring bar. A thin piece of polyvinyl tubing connects the mixing flask with the gradient tube. A small syringe is attached to the mixing chamber through a short piece of tubing to adjust in a reproducible way the amount of pressure at the beginning. The mixing flask is now filled with sucrose solution of a concentration  $C_t$  equal to that desired at the top of the gradient. The mixing volume  $V_m$  is determined by the type of isokinetic gradient to be chosen (Table 1) and remains constant. The procedure is started by increasing the air pressure in the mixing chamber with the syringe until the solution has risen to a fixed point in the ascending portion of the outlet tubing. The tubing between the burette and mixing flask is then clamped off. The stopcock of the burette is opened to add the heavy sucrose solution with rapid stirring at a rate of about 1.0 ml/min. As the volume  $V$  added from the burette increases, a corresponding volume of the mixture is displaced into the gradient tube. The total volume added to the centrifuge tubes of the IEC rotor 283 used in these experiments was 12.0 ml. To prevent turbulence in the gradient tube, the end of the outlet tubing from the mixing chamber is inserted into a capillary pipette whose tip must touch the bottom of the gradient tube, so that the light sucrose introduced first is allowed to float to the top, as solution of increasing density is fed in. At the end of the procedure the capillary pipette is carefully pulled out through the gradient. The gradients, prepared at room temperature, were precooled to  $2^\circ\text{C}$  by storing in the cold room before use.

This equation is transcendental, and cannot be solved explicitly for  $C$ . The function  $C=f(r)$  may be evaluated by computer or graphical methods. The graphically determined solutions of  $C$  for various values of  $r$  have been plotted against  $r$  (or the equivalent volume units of the gradient tube) in Fig. 1. In this example a particle density of  $D_p=1.51$  and a top concentration of 15 per cent have been selected. Evidently, different isokinetic curves will be obtained for other top concentrations, particle densities and rotor dimensions.

For the experimental application of the principle of constant velocity sedimentation, a method of preparing the calculated gradients is needed. The constant velocity gradient in Fig. 1 exhibits a convex curvature. Convex exponential gradients in which the sucrose concentration  $C_v$  increases as a function of the volume  $V$  according to

$$C_v = C_R - (C_R - C_t) e^{-V/V_m} \quad (6)$$

can be generated by a simple gradient maker consisting of burette and mixing flask (Fig. 2). By a suitable choice of the mixing volume  $V_m$  and the concentration of the sucrose solution  $C_R$  in the reservoir, one of the curves described by equation (6) will (for a given  $C_t$ ) very closely approach the theoretical constant velocity sedimentation gradient of equation (5). By a simple mathematical procedure (outlined in the legend to Fig. 1) the experimental gradient can easily be made to match the theoretical curve within 1 per cent or less as illustrated by way of an actual numerical example (Fig. 1).

Fig. 3. Sedimentation patterns of mouse liver polysomes in isokinetic gradient. Input: 4  $A_{260}$  units in 0.2 ml. Recorded after 1 h (top) and 2 h (bottom) centrifugation at 40k r.p.m. and 2° C. Gradient calculated for  $D_p = 1.4$  and  $C_T = 15$  per cent sucrose. The strongest peak corresponds to the 80S monomer species. Centrifugations were carried out with the 6 × 14 ml. swinging bucket rotor No. 283 in a B-60 ultracentrifuge of the International Equipment Company. The centrifuge was set to the desired top speed and decelerated with the automatic brake on. The gradient tubes were punctured and the absorbancy of the effluent at 260 mμ was scanned and recorded automatically\* with the IEC-Gilford high resolution gradient analysing system. The design and components of this system, which is capable of resolving particles differing by less than 7 per cent in sedimentation coefficient, will be described in detail later. Sedimentation rates were determined from the strip chart recordings by measuring the distance between the peak centre and the top of the gradient. To indicate the top of the gradient, 0.2 ml. of a 0.2 molar sucrose solution containing 0.5 mg/ml. of RNA as an absorbancy marker was layered over the gradient immediately before collection (peak on extreme right).

Thus for a given top concentration, temperature and rotor only the particle density  $D_p$  is needed to select the proper mixing volume  $V_m$  and reservoir concentration  $C_R$  for preparing the desired isokinetic gradient. I have tabulated the parameters ( $V_m, C_R$ ) covering the useful range of particle densities from 1.2 to 1.8 (Table 1). These data have been calculated for a top concentration of 15 per cent, a temperature of 2° C and the 6 × 14 ml. swinging bucket rotors SB-206 and 283 of the International Equipment Company. The results of a computer programme giving the pertinent data for other top concentrations, temperatures and the variety of commercially available rotors are to be published.

1.7	9.0	32.8	0.96	15
1.8	9.0	33.2	0.97	15

\* The volume added from the burette to the tubes is 12.0 ml.

† Concentration near the bottom of the gradient.

The most obvious advantage of the constant velocity sedimentation method is the ease with which it permits the determination of sedimentation constants. Thus the  $S$  value of an unknown macromolecule is immediately obtained from its mobility ratio with respect to an internal standard of equal density after a suitable period of centrifugation

$$S_{20,w}(\text{unknown})/S_{20,w}(\text{standard}) = R_U/R_S \quad (7)$$

According to equation (1) the method lends itself equally well to the determination of absolute sedimentation values. Because  $dr/dt$  is constant, the sedimentation coefficient is directly obtained by measuring the distance  $R$  the object has travelled from the start during the centrifugation time  $t$  at an average angular velocity  $\omega^2$

$$S_{20,w} = (R/t)(A/K)\omega^{-2} \quad (8)$$

in which

$$K = (D_p - D_t)r_t/\eta_t$$

The validity of the concept was tested in experiments illustrated in Figs. 3 and 4. Polysomes from mouse liver were centrifuged for 1.0 and 2.0 h at 2° C and 40k r.p.m. in the SB-283 rotor of a B-60 International ultracentrifuge. Mammalian ribosomes have been reported to have a density of 1.5 (ref. 12), and so constant velocity sedimentation gradients corresponding to  $D_p = 1.4, 1.5$  and 1.6 were used. The strip chart recordings of the sedimentation patterns in Fig. 3 show that the resolution is excellent and that with increasing time of centrifugation the separation between peaks continues to increase throughout the whole length of the tube, in contrast to the piling up of the components toward the bottom observed in conventional gradients.

According to theory, a plot of the distance travelled by the various polysome species against  $S \times t$  should give a straight line, if the sedimentation rate is constant throughout the gradient. The results in Fig. 4 are in excellent agreement with this prediction. To compute the  $S \times t$  values, an average of published  $S$  values<sup>6,12,14</sup> for mammalian polysomes (80S)<sub>n</sub>,  $n = 1-8$ , were used and the time factor was corrected for the contribution of acceleration and deceleration. There was no significant deviation from linearity in gradients calculated for  $D_p =$

Fig. 4. Test for constancy of polysome sedimentation rates in isokinetic gradient. Mobilities of polysome peaks determined from recordings in Fig. 3 are plotted against  $S \times t$ . Monomer to tetramer: 80S  $\Delta$ , 119S  $\circ$ , 152S  $\square$ , 180S  $\nabla$  (solid symbols = 1 h, open symbols = 2 h); pentamer to octamer: 207S  $\blacklozenge$ , 230S  $\circ$ , 258S  $\blacksquare$ , 281S  $\blacklozenge$  (all 1 h).

1.4 and 1.6. As evident from Table 1, the precision of this parameter is not very critical, for the maximal concentration difference between these two gradients (at the bottom) is only 4 per cent.

An example illustrating the value of the method for the determination of absolute sedimentation coefficients is summarized in Table 2. The results obtained for repre-

Table 2. DETERMINATION OF  $S_{20,w}$  VALUES FOR RIBOSOMAL RNA FROM VARIOUS SOURCES

rRNA	Rat liver		Bean, cytoplasm		Bean, chloroplast	
	a	b	a	b	a	b
R (cm)	4.63	2.73	3.81	2.47	3.35	2.53
$S_{20,w}$	30.2	17.8	24.9	16.1	21.8	16.5

The  $S_{20,w}$  values were determined according to equation (8) using the following numerical values:  $t = 3.96 \times 10^4$  sec (11 h),  $\omega^2 = 1.75 \times 10^7$  (40k r.p.m.),  $r_1 = 6.8$  cm,  $D\rho = 1.7$ ,  $D_1 = 1.063$ ,  $D_{20,w} = 1.00$ ,  $\eta_1 = 2.83$ ,  $\eta_{20,w} = 1.00$ .

sentatives of the three known classes of ribosomal RNA<sup>7</sup> agree well with the values determined previously by the internal standard method in sucrose gradients<sup>7</sup> or by moving boundary analyses in the analytical ultracentrifuge<sup>15-17</sup>. It should be pointed out that the accuracy depends most critically on the precision of measuring  $\omega^2$  and good temperature control.

The method of constant velocity sedimentation introduced here describes a new type of gradient designed to keep the forces acting on the sedimenting particles constant over the entire path length. The theoretical shape of this gradient is specific for a given rotor, particle density and temperature, and can be approximated by a simple device consisting of burette and mixing flask. Once the appropriate parameters have been determined, isokinetic gradients can be prepared routinely with no more effort than conventional gradients. The new method greatly facilitates the quantitative evaluation of sedimentation behaviour and permits better separation of components with similar sedimentation rates, for differences in mobilities continue to increase at a linear rate throughout the whole length of the tube.

Although the gradients described here are strictly isokinetic only for spherical objects the density and shape of which are not affected by the change in concentration of

sucrose, no significant deviations from constant velocity were detected in sedimentation tests with ribosomes and ribosomal RNA. Furthermore, a comparison of curves corresponding to isokinetic gradients calculated for various densities reveals that relatively large changes in particle densities would have to occur during sedimentation to cause a detectable deviation from the constant velocity path. These observations suggest that isokinetic sedimentation would be of general usefulness for the characterization of a wide variety of macromolecules. Replacement of the many individual and largely arbitrary gradients now in use by the adoption of this method would eliminate much undesirable variation and provide a common standard for the comparison and interpretation of results obtained in different laboratories.

I thank Dr E. Stutz for preparing and centrifuging the rRNA samples and Mrs N. Shoemaker for technical assistance.

## Diversity of RNA Components in Green Plant Tissues

by  
U. E. LOENING  
J. INGLE

Department of Botany,  
University of Edinburgh

Gel electrophoresis of ribosomal RNA from green plant tissues provides evidence consistent with the suggestion that chloroplasts have evolved from symbiotic blue-green algae, while the plant cytoplasmic RNA is distinct from both the bacterial and mammalian.

THE presence of two distinct ribosome species, approximately 80S and 70S, has been demonstrated in leaf tissue from spinach<sup>1</sup>, Chinese cabbage<sup>2</sup>, peas<sup>3</sup>, tobacco<sup>4</sup>, and beans<sup>5</sup>. The 80S species, similar in size to animal ribosomes, is the normal cytoplasmic ribosome whereas the 70S, similar to bacterial ribosomes, is restricted to the chloroplast. These observations suggest that the ribosomal RNAs of the chloroplast may be smaller than those of the cytoplasm. Detailed information has not been obtained by conventional fractionation procedures, and so we have investigated this problem using the high resolution of RNA fractionation achieved by gel electrophoresis.

Previous work using fractionation on methylated-albumin, kieselguhr columns showed that total RNA prepared from green radish cotyledons was very different

from the RNA of root tips or other non-green tissues. Three or four high molecular weight components instead of the normal two ribosomal RNAs were partially resolved, and four low molecular weight components were present compared with the normal two from non-green tissues (our unpublished results). Although this method of fractionation only partially separates the high molecular weight RNAs it has been successfully used to investigate the cellular origin of the low molecular weight components. Two of these components were unique to the chloroplast, one to the cytoplasm, while the fourth, the transfer-RNA, was present in both<sup>6</sup>.

Sucrose density centrifugation has been used in several studies on the RNA of tissues containing chloroplasts. Chloroplasts from *Euglena* contained two RNA components, 19S and 14S, whereas the cytoplasm contained

Fig. 1. Gel fractionation of nucleic acids from radish. Fifty radish seedlings, grown in the light for 6 days, were separated into roots (A), hypocotyls (B) and cotyledons (C), and total nucleic acids were prepared by method A. See Fig. 6 for the assignment of *S* values.

only the 19S component<sup>7</sup>. These sedimentation patterns, however, showed evidence of degradation. The chloroplast and cytoplasmic RNAs from *Euglena* had very different base compositions<sup>7</sup>. Chloroplast RNA from *Acetabularia* had two components similar in size to non-chloroplast RNA (ref. 8). RNA prepared from lettuce chloroplasts was not distinguished from the cytoplasmic ribosomal RNA by sucrose gradient centrifugation and only very small differences in composition were observed<sup>9</sup>. Sucrose gradient analysis of RNA prepared from chloroplasts of spinach, tobacco, radish, pea and tomato leaves showed only a single 16S component, whereas RNA from the whole leaf and from cytoplasmic ribosomes was resolved into 25S and 16S components<sup>10</sup>. Again, no significant difference in base composition was noted between chloroplast and cytoplasmic RNAs<sup>10</sup>. Stutz and Noll<sup>5</sup> have, however, been able to separate three high molecular weight RNA components from a mixture of cytoplasmic and chloroplast ribosomes from bean leaves. They suggested sedimentation constants of 25 and 16 for the cytoplasmic ribosomal RNAs, and 23 and 16 for the corresponding components from the chloroplast. It is interesting to note that in all these investigations the chloroplast preparations contained as much, or more, 16S than 23S RNA, whereas cytoplasmic ribosomal RNAs are present with a ratio of heavy to light components of approximately 2:1.

In the present investigation the very high resolution of RNA fractionation achieved by polyacrylamide gel electrophoresis<sup>11</sup> has been used to investigate this problem in relation to the high molecular weight components. Gels were prepared (in 7.5 × 0.63 cm 'Perspex' tubes) containing 2.4 per cent acrylamide (recrystallized from chloroform) and 0.12 per cent bisacrylamide (recrystallized from ace-

Fig. 2. Comparison of nucleic acids from green and non-green tissues. A, French bean leaf, 8 days (method A); B, lettuce leaf (method B); C, cocklebur leaf (method A); D, corn leaf (method A); E, pea leaf (method A); F, barley leaf (method B); G, pea root tips (method A); H, artichoke tuber tissue (method B).

tone). The buffer contained 36 mmolar *tris* ('Trisma', Sigma), 30 mmolar sodium dihydrogen phosphate and 1 mmolar ethylenediamine tetra-acetic acid. Sodium lauryl sulphate (B.D.H. 'specially purified' grade) was added to the buffer compartments at a concentration of 0.2 per cent, and allowed to enter the gels during pre-electrophoresis at 6.5 V/cm, 5 m.amp for each tube at room temperature (20° C) for 20–40 min. The gel tubes were completely immersed in the buffer for cooling,

Fig. 3. Changes in nucleic acids during development of the French bean leaf. Nucleic acids were prepared by method B from the first pair of leaves from 4 (A), 5 (B), 6 (C), 8 (D) and 10 day old (E) light grown seedlings. Nucleic acids were also extracted from leaves of 7-day-old dark grown seedlings (F).

Fig. 4. Chloroplast nucleic acids. Nucleic acids were prepared from the whole leaf (A) and from the chloroplast fraction (B). Leaves from 8-day-old French bean seedlings were ground by pestle and mortar at 0° C in a medium containing 0.4 molar mannitol, 50 mmolar *tris*, 50 mmolar potassium chloride, 5 mmolar magnesium acetate, 0.1 per cent bovine serum albumin and 0.1 mg/ml. of Cleland reagent, pH 7.8 at 0° C. The homogenate was filtered through cheese cloth and centrifuged at 100g for 4 min. The supernatant was centrifuged at 1,000g for 5 min to pellet the chloroplasts. The chloroplasts were washed by resuspending in the medium and collected by centrifugation at 1,000g for 5 min. The pellet was suspended in a medium containing 1 per cent tri-isopropyl-naphthalene sulphonate, 6 per cent *p*-amino-salicylate and 1 per cent sodium chloride, and nucleic acid was extracted with phenol, as described in the text.

RNA was dissolved in the electrophoresis buffer supplemented with 0.2 per cent sodium lauryl sulphate and 5 per cent sucrose at a concentration of about 1 mg/ml., and 25  $\mu$ l. layered on the gel. Electrophoresis was continued for 2–3 h, by which time the soluble RNA had run off the gel. The gels were then removed from the tubes, rinsed in water for 5–30 min and scanned at 265 m $\mu$  using the Joyce Loebel 'Chromoscan'. The background optical density of the gels at this wavelength was 0.20.

Two main methods were used to prepare total nucleic acid from plant tissue. In method A the fresh tissue (approximately 1 g) was homogenized at 0° C for 10 sec at top speed (45,000 r.p.m.) in a Virtis '45' homogenizer in 10 mmolar *tris*, pH 7.4, containing 1 per cent sodium lauryl sulphate and 12 mg/ml. of bentonite plus an equal volume of phenol containing 0.1 per cent 8-hydroxyquinoline and 10 per cent *m*-cresol. After centrifugation the lower phenol layer was removed to leave the interphase and aqueous layer to which sodium chloride (final concentration, 0.5 molar) and an equal volume of phenol mixture were added. After mixing and centrifuging, the top aqueous layer was removed and extracted once more with phenol. Two volumes of ethanol were added to precipitate the nucleic acids from the final aqueous layer. The precipitate was dissolved in 0.15 molar sodium acetate, pH 6.0, containing 0.5 per cent sodium lauryl sulphate, and reprecipitated with two volumes of ethanol. After centrifugation the pellet was washed with cold 80 per cent ethanol, partially dried and dissolved in the electro-

phoresis buffer. In method B (modified from Kirby<sup>12</sup>) the tissue was homogenized in the Virtis as described here in 10 mmolar *tris*, pH 7.6, containing 50 mmolar sodium chloride and 0.5 per cent naphthalene 1:5 disulphonate. This medium inhibits nucleases while preventing the release and shearing of DNA. Tri-isopropyl-naphthalene sulphonate and *p*-amino-salicylate were then added to final concentrations of 1 per cent and 6 per cent respectively. An equal volume of the phenol mixture was added and thereafter the procedure was as described in method A. The two methods of preparation gave identical RNA patterns on gel electrophoresis, although the DNA was considerably sheared by method A, and gave a much broader peak.

Fractionation of total nucleic acid prepared from radish root and hypocotyl tissues showed the normal distribution of two ribosomal RNAs (Fig. 1A, B). The green cotyledons from the same radish seedlings contained, however, two additional major and one minor RNA component (Fig. 1C). These components have been assigned sedimentation constants of 25, 23, 18, 16 and 13 as described below (see Fig. 6D). Total nucleic acid has been extracted from radish cotyledons by the two methods described, and by several modifications of these procedures including milder homogenization with pestle and mortar and with 'Teflon' in glass. All extraction methods gave identical results for the electrophoretic pattern of the RNA components. The additional RNA components, 23S and 16S, were present in all of the green material examined (Fig. 2A, B, C, D, E, F) constituting about 30 per cent of the high molecular weight RNA, and were absent from non-green tissues (Fig. 2G, H). The minor components present in non-green tissues have not been investigated, but they may be plastid or perhaps mitochondrial RNA.

Fig. 5. Degradation of nucleic acids during cell fractionation. Nucleic acids were prepared from 6-day-old radish cotyledons (A) and from the same tissue after homogenization and centrifugation (B). The tissue was homogenized in the Virtis for 10 sec at top speed in the medium described by Stutz and Noll<sup>5</sup>. The homogenate was centrifuged at 200,000g for 90 min and nucleic acids were prepared from the pellet by method A.

Fig. 6. Size of plant cytoplasmic RNAs compared with mammalian and bacterial ribosomal RNAs. A, HeLa cell RNA; B, *E. coli* RNA; C, pea root tip RNA; D, mixture of HeLa, *E. coli* and pea root tip RNAs. Ten centimetre gels were used, and electrophoresis was continued for 4 h to obtain greater separation. The electrophoretic mobilities of the RNA components were related to sedimentation constants, assuming values of 29/18 and 23/16 for the HeLa and *E. coli* RNAs respectively (D).

The relative proportions of the components varied with the developmental stage of the tissue. Fig. 3 shows the changes in total nucleic acid during development of the French bean leaf. The 23S and 16S components increased relative to the 25S and 18S RNAs during growth and maturation of the leaf, increasing from 10 per cent to 30 per cent of the total RNA. In addition, minor components of 21S, 15S and 13S appeared during development. These changes were not seen in leaves of plants grown in the dark (Fig. 3F). Similar developmental patterns have been observed with radish cotyledons and with cocklebur leaves.

The presence of these additional RNA components in green compared with non-green tissues suggests that they are associated with the chloroplast. RNA prepared from chloroplasts isolated from bean leaves showed an eight-fold enrichment of the 23S, 16S and minor components (Fig. 4). Considerable degradation of the RNA can occur during the separation of cell organelles by homogenization and differential centrifugation. Such degradation varied markedly with different tissues. So far it has been impossible to prepare RNA from isolated radish chloroplasts without loss of most of the 23S component. Such cases of degradation were usually accompanied by a large increase in 13S material (Fig. 5), and there is doubt therefore about the origin of this 13S component. Absence of a 23S component has also been noted with chloroplasts from spinach, tobacco, radish, pea and tomato leaves<sup>10</sup>. In the French bean, however, the relative proportions of the 23S, 21S, 16S, 15S and 13S components present in the total RNA preparation were maintained during isolation of the chloroplasts by a variety of methods. Consequently these components are thought to be true constituents of the bean chloroplast.

A peculiarity of the chloroplast is that there is more 16S than 23S RNA. This occurred in total nucleic acid preparations and with RNA from isolated chloroplasts, although the ratio of cytoplasmic 25S to 18S RNA was approximately two. This molar excess of 16S to 23S RNA has been observed in almost all chloroplast RNA studies<sup>5,7-10</sup>.

Gradual breakdown of the cytoplasmic RNA also occurred during cell fractionation. The first indication of degradation with leaf RNA was a broadening and loss of the 18S component accompanied by the appearance of a 17S peak (Fig. 5). The occurrence of such degradation, which could be missed by sucrose gradient analysis, was easily recognized because of the very high resolution of RNA fractionation by this electrophoretic method.

The sizes of the RNA components of the plants were compared with mammalian and bacterial RNAs (Figs. 6 and 7). A mixture of HeLa, pea root tip and *E. coli* RNA was fractionated (Fig. 6). The heavy ribosomal RNA from the plant cytoplasm (Fig. 6C) moved at a rate intermediate between those of the mammalian and bacterial components, while the lighter component moved at a rate similar to that from the mammalian ribosome. For convenience of comparison with other work we have related the electrophoretic mobilities to sedimentation constants, assuming mammalian and bacterial ribosomal RNAs to be 29S/18S and 23S/16S respectively. For this range of molecular size, and with the concentration of gel used, the sedimentation constants showed an inverse linear relationship to their mobilities in the gel (Fig. 6D). From this relationship the constants for the plant cytoplasmic components were found to be 25 and 18. The RNAs from the chloroplast had mobilities similar to the ribosomal RNAs of bacteria, namely, 23S and 16S (Fig. 7A, B). The resolution achieved in these conditions of electrophoresis (Fig. 6D) would show differences of 0.2S.

Fig. 7. Size of plant chloroplast RNAs compared with bacterial and blue green algal RNAs. A, Nucleic acids from 8-day-old French bean leaf; B, French bean leaf plus *E. coli* RNAs; C, pea root tip (p) plus a species of *Oscillatoria* (o) RNAs.

These results support the contention that three distinct classes of ribosomes exist: 80S in mammalian cells, containing 29S and 18S RNA; 80S in the plant cytoplasm, containing 25S and 18S RNA; and 70S in bacteria and plant chloroplasts, containing 23S and 16S RNA.

Our data contrast in part with those of Stutz and Noll<sup>5</sup>, who concluded that the lighter plant cytoplasmic component was smaller than the mammalian 18S RNA and similar to the bacterial and chloroplast 16S component. The resolution obtained by zone velocity centrifugation<sup>5</sup>, however, was not sufficient to show with any certainty whether degradation, such as the production of 17S from 18S (Fig. 5), had occurred during the long time involved in the preparation of the ribosomes. The discrepancy may also arise from the different methods used, for it is likely that the secondary structure of the molecule affects electrophoretic mobility and sedimentation in different ways. Such behaviour has been noted with tobacco mosaic virus RNA, which, with a sedimentation constant of 26–28, has a very low mobility on electrophoresis compared with 28S or 25S ribosomal RNA. Electrophoretic mobility on the gel is more directly related to log molecular weight than is the sedimentation constant<sup>13</sup>. We conclude that both components of plant cytoplasmic ribosomal RNA are distinct from, and larger than, bacterial RNAs.

Similarities in structure between the blue green algal cell and the chloroplast have led to the suggestion that this cell organelle may have evolved from the capture of such a lower organism. It has been demonstrated that blue green algae contain 70S ribosomes<sup>14</sup> similar to bacteria and chloroplasts. We have examined the RNA from a species of the blue green alga *Oscillatoria* and found it to be the same size as bacterial and chloroplast RNAs (Fig. 7C). This lends further support to the evolutionary hypothesis.

## Effect of Anti-rat Lymphocyte Antibody on Humoral Antibody Formation

by

K. JAMES

V. S. JUBB

Experimental Problems of Transplantation,  
The Medical School,  
Edinburgh

Horse anti-rat lymphocyte IgG globulin suppresses and/or delays the primary response to alum-precipitated bovine serum albumin in hooded rats. This material does not have a marked effect on the secondary response of sensitized animals.

RECENT work has shown that anti-lymphocytic sera (ALS) are effective immunosuppressive agents prolonging the survival of skin homografts in rats<sup>1,2,15</sup> and mice<sup>3–5</sup> and renal homotransplants in dogs<sup>6–8</sup> and humans<sup>9</sup>. In addition, anti-lymphocytic antibody has been shown to suppress significantly the primary humoral antibody response of both rats<sup>9</sup> and mice<sup>3</sup> to sheep erythrocytes and possibly to exert a slight effect on the secondary response<sup>3,9</sup>. The present report is a detailed study of the effect of anti-lymphocytic IgG on the production of humoral antibody in hooded rats after primary and secondary stimulation with a further commonly used test antigen, namely alum precipitated bovine serum albumin (BSA). Throughout the investigations the humoral antibody response has been assessed by measuring the antigen binding capacity (ABC) of the rat sera by means of the sensitive ammonium sulphate method of Farr<sup>10</sup> which measures the primary interaction of antigen and antibody.

Details of the production of the horse antiserum to thoracic duct lymphocytes, and the isolation and assay of the IgG preparations used, have already been reported<sup>9</sup>. The reciprocal lymphocyte agglutination and lymphocytotoxic titres of the anti-lymphocytic IgG were both 256, while those of the normal IgG were less than 8.

The alum precipitated bovine serum albumin for injection (Armour Pharmaceutical Company, Lot Nos. C4101) was prepared as described by Pinckard, Weir and McBride<sup>11</sup>. Soluble BSA iodinated with iodine-131, for

use in the Farr procedure, was prepared by the chloramine-T method described by Hunter and Greenwood<sup>12</sup> using carrier-free iodine-131. The nitrogen content of the labelled BSA was determined by the micro-Kjeldahl procedure<sup>13</sup>. The labelled BSA preparations were used only if more than 96 per cent of the radioactivity was precipitated with 10 per cent trichloroacetic acid (TCA). The antibody content of the rat sera obtained following antigenic stimulation was assessed by the Farr procedure<sup>10</sup>. This technique was performed exactly as described by Pinckard, Weir and McBride<sup>11</sup>, using appropriate normal serum controls. The antigen binding capacities recorded in Table 1 and plotted in Figs. 1 and 2 were obtained with bovine serum albumin samples containing 0.2 µg nitrogen and are expressed in terms of the number of micrograms of nitrogen bound by 1 ml. of undiluted serum. In order to measure the relative binding affinity (a measure of the quality of the antibody produced) the antigen binding capacity was also determined using samples containing 0.02 µg of bovine serum albumin nitrogen. The latter ABC value was divided by the value obtained using 0.2 µg nitrogen and expressed as a percentage value. As the affinity of the antibody increases, the value obtained approaches 100 per cent. Throughout the investigations all samples were counted in a well-type scintillation spectrometer with a 2 in. sodium iodide crystal.

The effect of anti-lymphocytic IgG on the immune response to alum precipitated BSA was investigated in

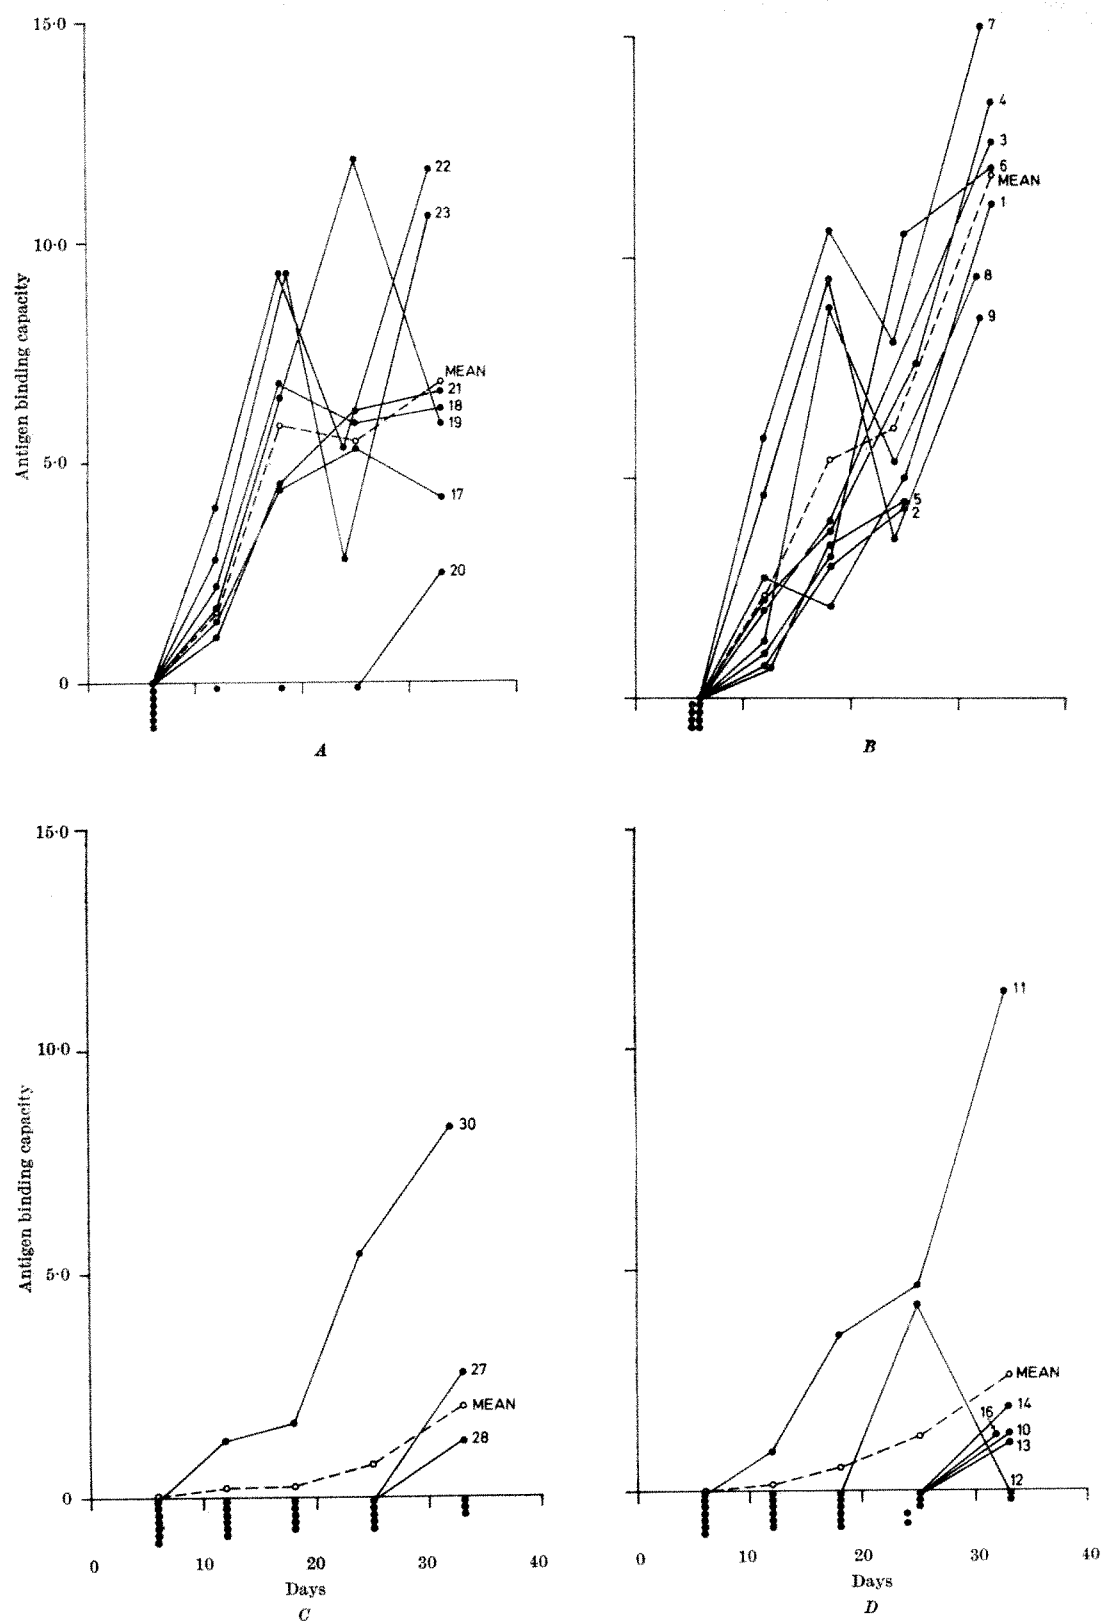

Fig. 1. Effect of normal IgG and anti-lymphocytic IgG on the primary immune response of hooded rats to alum precipitated bovine serum albumin. *A*, Experimental group 1A, male rats receiving normal IgG; *B*, experimental group 1B, female rats receiving normal IgG; *C*, experimental group 1C, male rats receiving anti-lymphocytic IgG; *D*, experimental group 1D, female rats receiving anti-lymphocytic IgG. The experimental groups were divided into male and female for ease of presentation of results. The circles under the base-line represent animals in which the immune response was so weak that ABC values could not be obtained using a bovine serum albumin test sample containing 0.2  $\mu$ g nitrogen. In some groups the number of samples varies slightly from bleed to bleed and this is due to deaths and the occasional inability to obtain sufficient sera for analysis.

hooded strain male and female rats. The animals received intraperitoneal injections of sterile normal horse IgG (experimental groups 1A and 1B—see Table 1) or anti-lymphocytic IgG (experimental groups 1C and 1D) on days -3, -2 and -1 and were injected intraperitoneally on day 0 with 5 mg of alum precipitated BSA. The animals were then bled at intervals of 6 days. After 30 days the rats in groups 1A and 1B were subdivided, half the rats in each group receiving a further course of normal IgG (experimental group 2A) and the other half anti-lymphocytic IgG (experimental group 2B). Similarly half the rats in group 1C and 1D received normal IgG (experimental group 2C) and the other half anti-lymphocytic IgG (experimental group 2D). These injections were given on days 30, 31 and 32 and the animals were rechallenged intraperitoneally with 5 mg of alum precipitated BSA on day 33. The animals were then bled at 7 day intervals. All the serum samples obtained were

stored at  $-20^{\circ}\text{C}$  until analysed. Further details on the animals used and the course of treatment are given in Table 1.

The effect of the normal and anti-lymphocytic IgG preparations on the primary response of individual hooded male and female rats is shown in Figs. 1A to 1D and summarized in Table 1. It is seen that anti-lymphocytic antibody causes a marked suppression and delay in humoral antibody formation in most of the rats studied (Figs. 1C and 1D). This suppression was also associated with a significant reduction in the peripheral blood lymphocyte count (Table 1). Anti-lymphocytic IgG did not markedly inhibit humoral antibody formation in all the rats studied, however, for two out of fourteen (that is, rat No. 30, see Fig. 1C, and rat No. 11, see Fig. 1D) showed a response of similar magnitude to that found in rats pretreated with normal IgG. It should also be noted that on day 33 all the sera from rats treated with anti-

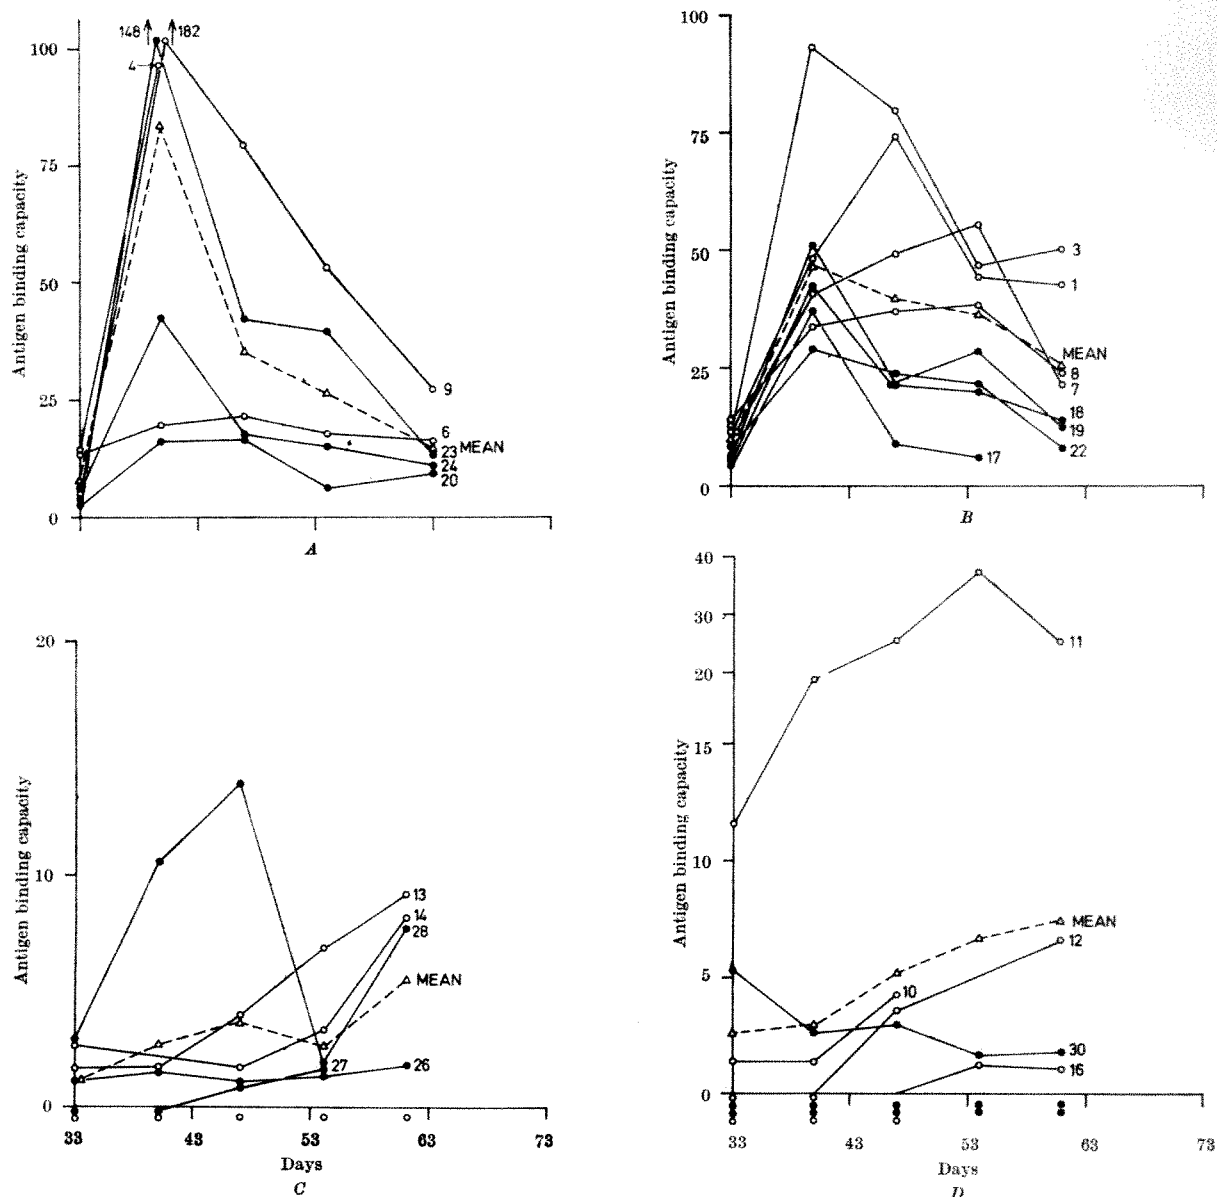

Fig. 2. Effect of normal IgG and anti-lymphocytic IgG on the secondary response of hooded rats (from groups 1A to 1D) to alum precipitated bovine serum albumin. ●, Male; ○, female. A, Experimental group 2A, rats receiving normal IgG before primary and secondary antigenic challenge with alum precipitated bovine serum albumin; B, experimental group 2B, rats receiving normal IgG before the primary and anti-lymphocytic IgG before the secondary antigenic challenge; C, experimental group 2C, rats receiving anti-lymphocytic IgG before the primary and normal IgG before the secondary antigenic challenge; D, experimental group 2D, rats receiving anti-lymphocytic IgG before the primary and secondary antigenic challenge. For further details see Fig. 1, Table 1 and text.

Table 1. PRETREATMENT OF HOODED RATS AND ITS EFFECT ON HUMORAL ANTIBODY PRODUCTION

Response	Experimental group		Rats				IgG treatment		Peripheral blood lymphocyte count (total and %)		Antigen binding capacity (0.2 µg nitrogen)	
			Sex	Nos.	Mean wt. (g)	Wt. range			-3	0	Initial	Maximum observed*
									Day or 30	Day or 33		
Primary	1A	{	Male	7	213	180-275	3 ml.	1 g% normal	3,720 (100)	3,550 (95)	0	7.9 ± 1.3

	2C	{	Rats from groups 1C and 1D	female	{	6	3 ml.	1 g% normal	3,075 (100)	3,135 (102)	1.2 ± 0.4 (100 ± 30)	5.8 ± 2.4 (580 ± 200)
	2D			7		3 ml.			1 g% ALS	3,850 (100)	2,960 (76)	2.6 ± 1.9 (100 ± 53)

\* The antigen binding capacities are expressed as mean values together with the standard deviation of the mean. In primary response studies these values were calculated only from rats which had survived the entire experimental period. In the secondary response all rats were considered because very few died and these had usually reached a maximum. The secondary values are also expressed as a percentage of the starting antigen binding capacity of the appropriate experimental group.

lymphocytic IgG contained detectable amounts of anti-BSA antibodies although the levels were not always high enough to allow the determination of antigen binding capacities (that is, a 1/10 dilution of the serum failed to bind 33 per cent of the test antigen<sup>10,11</sup>). In those cases in groups 1C and 1D where antigen binding capacities were measurable on day 33 the relative binding affinities were similar to those observed on day 12 in animals receiving normal IgG (experimental groups 1A and 1B). Thus although there was usually a decrease and delay in antibody production, the antibodies eventually produced appeared to be qualitatively comparable with those initially observed in "non-suppressed" animals.

As previously noted in experiments studying the response of rats and mice to sheep erythrocytes<sup>2,9</sup>, the effect of anti-lymphocytic IgG on the secondary response was not very marked. Indeed, it is quite apparent from Table 1 and Fig. 2B (experimental group 2B) that animals which had received normal IgG before the initial injection of alum BSA responded readily to a further injection of alum BSA whether or not this was preceded by injection of anti-lymphocytic IgG. Analysis of the results suggests, on the other hand, that anti-lymphocytic IgG may be influencing quantitative aspects of the secondary response in a number of animals. In support of this there was also a slight indication that the relative response to a secondary challenge in rats which had initially received anti-lymphocytic antibody was also reduced when they received a further course of anti-lymphocytic IgG before the secondary stimulus (experimental group 2D). In order to establish whether anti-lymphocytic IgG does influence the magnitude of the secondary response, experiments will have to be carried out using more animals.

The anti-lymphocytic IgG had no obvious effect on the relative binding affinities of the antibodies produced after secondary stimulation in animals which had received normal IgG before primary stimulation. In experimental groups 2A and 2B the relative binding affinities usually showed marked increases after secondary stimulation. On the other hand, the relative binding affinities in groups 2C and 2D (those that had received anti-lymphocytic IgG before primary challenge) rarely showed the high values observed in groups 2A and 2B, thus indicating qualitative as well as quantitative differences in antibody production.

It is clear from these results that anti-lymphocytic IgG suppresses and/or delays the primary response of hooded rats to alum precipitated BSA, in addition to inhibiting erythrocyte agglutinin formation in rats and mice<sup>3,9</sup>. Thus this material affects the onset of both humoral and cellular types of immunity (see homograft experiments with this preparation<sup>14,15</sup>).

It has still to be determined whether anti-lymphocytic antibody interferes with the sensitizing ("triggering")

phase of antibody production and/or the proliferative phase. A number of theories have been postulated to explain how this material could affect either, or both, of the processes. These include lymphocytolysis, the "sticky antigen" theory, blindfolding of lymphocytes<sup>1</sup> and sterile inactivation<sup>5</sup>. Whatever mechanisms are operating, it is clear that the present course of treatment, although it caused suppression, did not produce complete tolerance; all the animals receiving anti-lymphocytic antibody eventually produced detectable amounts of anti-BSA antibodies and also responded to a secondary challenge with BSA. Thus either the animals recovered their capacity to recognize and process antigen (the sensitization phase) and/or their ability to produce antibody after antigenic recognition (proliferative phase). This could result from the original cells recovering their immunological capacity or the maturation of additional immunologically competent cells or a combination of these and other phenomena. Cytological investigation<sup>16</sup> of those cells which do survive anti-lymphocytic treatment suggests that "deformation" may have occurred. This could render them incapable of producing normal levels of antibody or developing into cells with this potential. Whatever the explanation, it appears from measurements of relative binding affinity that the antibodies eventually produced after primary stimulation are qualitatively similar to those initially observed in animals receiving normal horse IgG. On the other hand, the affinities of the antibodies produced after secondary stimulation in group 2C and 2D were appreciably lower than those observed in animals which had received normal IgG before primary stimulation (group 2A and 2B).

The failure effectively to suppress the secondary response in "sensitized" animals (that is, those from group 1A and 1B) indicates that the course of treatment used did not "abrogate the pre-existing state of immunity to alum precipitated BSA", a phenomenon observed in relation to the survival of second set homografts<sup>4,5</sup>. Thus in these studies the anti-lymphocytic IgG failed to destroy immunological memory by inactivating memory cells. Nevertheless the results suggest that this form of treatment may be affecting the quantity, though not the quality, of the antibody produced after secondary stimulation in "sensitized" animals.

These investigations also indicate that gross lymphocyte depletion is not a prerequisite for effective immunosuppression<sup>4,9</sup>. Nevertheless, as previously suggested, the possibility that anti-lymphocytic antibody functions by destroying or inactivating a select proportion of vital cells cannot be precluded<sup>3,4,9</sup>. Indeed, it is also possible that this material may interfere with the activity of the macrophage, thus affecting sensitization.

In conclusion, it is apparent that anti-lymphocytic antibody is capable of suppressing or delaying primary

humoral antibody formation against alum precipitated BSA as well as cellular aspects of immunity, but the mechanisms involved in these important phenomena will require further investigation.

We thank R. N. Pinckard for demonstrating the Farr procedure, providing the  $^{131}\text{I}$ -BSA and for his invaluable advice. We are also grateful to Dr N. F. Anderson and Mr J. Watt for the production of the antiserum and Mr C. Shepley for preparing the diagrams. Finally we wish to thank Professor M. F. A. Woodruff for his advice and interest in this work.

## Crossover Model of Antibody Variability

by

H. L. K. WHITEHOUSE\*

Department of Botany,  
University of Cambridge

Several unsatisfactory models have been proposed to account for the variation in the primary structure of the polypeptide chains in the antibody molecule. A new model is proposed here; it is based on intrachromosomal crossing over during the development of plasma cells.

FOUR hypotheses have been suggested to account for the variation in the primary structure of the chains of polypeptides (one light and one heavy) which are thought to comprise the antibody molecule. Three models attribute the diversity of structure to variation in the DNA of the chromosome, and the fourth to abnormality in the mechanism of translation of messenger RNA into polypeptide.

The multiple gene hypothesis<sup>1,2</sup> seems untenable because the non-variable parts of the polypeptide chains show normal mutation and Mendelian segregation, implying determination by one gene. Dreyer and Bennett<sup>1</sup> explained this by supposing that the constant part of the polypeptide was determined by a virus or episome which became attached to one of the many alternative genes postulated to determine the variable part of the molecule. This seems unacceptable, however, because even within the variable part of the polypeptide chain there appears to be constant or relatively constant regions<sup>3</sup>. Doolittle<sup>4</sup> has pointed out that this hypothesis would require the same base substitutions to have occurred at corresponding positions in all the genes—a most unlikely occurrence.

The inverted duplication hypothesis<sup>5,6</sup> postulates somatic intrachromosomal crossing over between non-adjacent relatively inverted duplications within the gene for the light polypeptide chain (and similarly within the gene for the heavy chain). This was questioned by Milstein<sup>7</sup>, who pointed out that the observed variation in amino-acid sequence frequently fails to correspond with that expected from the reversed complements of triplets.

The hypermutation hypothesis has to account for the limitation of the variability to only a part of the light and heavy polypeptide chains. Some<sup>2,8</sup> favour separate genes for the constant and variable parts of the polypeptides, with enzyme joining of the resultant peptides. This seems untenable, however, because the light and heavy chains are synthesized as single processes<sup>9,10</sup>. This difficulty is avoided by postulating enzyme removal of one chain of the DNA in the appropriate part of the gene, followed by a defective repair mechanism, leading to mutations only in that part of it<sup>11</sup>. A similar model was proposed by

Dreyer and Bennett<sup>1</sup> but dismissed because the variable region of the light chain shows considerable resemblance between one antibody and another. This limited variability argues against hypermutation, because even single base substitutions within an average triplet will give rise to triplets coding for five to seven different amino-acids, yet the variation observed at any one position in the polypeptide seems often to be much less than this<sup>12</sup>. Furthermore, mutation must be controlled in such a way that addition or deletion of single nucleotides does not occur, because this would displace the reading-frame for the constant part of the gene. This is because the variable parts of both the light and heavy polypeptide chains are in the N-terminal halves, which are the first to be synthesized. A similar objection applies to some of the structural changes postulated by Smithies<sup>3,4</sup>.

The specialized translation hypothesis<sup>13</sup> involves unusual triplets in the DNA of the variable region, and changes in specificity in the activating enzymes of transfer RNA molecules, so that these triplets can code for diverse amino-acids. Particular amino-acids are not always replaced in other antibody molecules by the same one<sup>7</sup>, contrary to the prediction of this model, and several other reasons have been given for regarding the model as unlikely<sup>12</sup>.

Thus there is a paradox, and despite considerable progress in understanding the nature of the variability in antibody structure, all the hypotheses that have been put forward to account for it are improbable.

In attempting to resolve this paradox, there can be no doubt, as Watson<sup>14</sup> implied, that hypotheses of antibody variability based on recombination are the most attractive. The necessary variations in the DNA could then be of the kind, and at the positions, which selection had favoured. Furthermore, the potential variability would be inherited and would not depend for its origin in each individual on so unpredictable a process as mutation.

There is a relatively simple way in which antibody variation could arise through recombination and yet be inherited as if caused by single genes, one for the light chain and one for the heavy chain, as the data appear to require. The failure hitherto to consider a mechanism of the kind described here seems to be a result of the

\* Present address: Division of Biology, Southwest Center for Advanced Studies, Dallas, Texas.

Fig. 1. Diagram to show the postulated behaviour<sup>17</sup> of a gene and sixteen copies of it when messenger RNA is to be synthesized. The gene and copies are arranged in a consecutive linear sequence within one DNA molecule. The copies are matched against the master gene and then extend as a lampbrush loop. The model is based on that proposed by Callan<sup>16</sup>. The lines represent nucleotide chains. Wavy lines show the position of the operator of the gene. (A) Annealing; (C) correction of mispairing to correspond with that in the chain with the descending arrow; (D) dissociation; (L, N) neighbouring genes to M and its copies. (M) Master copy of gene; (O) breakage at operator; (T) breakage at terminus. 1-16, Sixteen copies of gene M. I suggest that in the structural genes for the antibody polypeptides some modifications of the scheme shown would be necessary to allow both chains of all the other copies to be matched against one of the two copies which had taken part in an intrachromosomal crossover.

assumption that mammalian chromosomes are organized in the same way as the hereditary material of bacteria and viruses. This assumption, for example, is implicit in the misleading use of the term chromosome for the bacterial or viral DNA thread. Here I use the term chromosome in the strict sense, excluding the DNA thread of bacteria and viruses (for which I have suggested the term chromoneme<sup>15</sup>).

There is a considerable body of evidence, reviewed by Callan<sup>16</sup>, in support of the hypothesis that in chromosomes each gene is duplicated  $2^n$  times consecutively within one DNA molecule, where  $n$  may vary independently for each gene according to the species, sub-species or population, but may be of the order of six to twelve for many genes in *Triturus*<sup>17</sup>. The set of copies would form a chromomere. Callan<sup>16</sup> has proposed a mechanism whereby the copies of each gene are matched against that which has undergone recombination with the homologue, with the result that all acquire identical nucleotide sequences. I have suggested<sup>17</sup> a modification of this mechanism which facilitates the coiling and uncoiling of nucleotide chains (see Fig. 1).

It seems possible that the matching may precede the synthesis of messenger RNA whenever this occurs.

For genes which do not function in the germ-line and which are therefore presumed not to undergo matching of the copies in the germ-line, it is possible that in special circumstances selection might favour the maintenance of slight differences between the copies, and it is suggested that this may have happened in the evolution of antibody variability. In the germ-line there would then be a number of related and consecutive antibody-gene nucleotide sequences which differed from one another, as a result of mutations accumulated in the course of evolution, and all of which would be handed down in their diversity from generation to generation. For differences between the gene copies to be advantageous it would be necessary, however, for the matching process to be modified, because this would normally eliminate any differences between the copies before the gene could function. It is suggested that in the development of plasma cells, before antibodies are synthesized, a crossover takes place within the chromosome between two of

the copies, and that this is followed by matching of the remaining copies against one of these two. This course of events is postulated for both antibody genes, that is, within the copies of the gene for the light chain, and, independently, within those for the heavy chain.

This intrachromosomal crossing over is similar to the postulated normal behaviour for all genes at the pachytene stage of meiosis, except that at meiosis it is suggested that the crossover always occurs between the first and last members of the series of copies<sup>17</sup> (see Fig. 2). Such a crossover would detach the copies as a ring (Fig. 2 (v)) and allow the one copy remaining in the chromatid to undergo normal crossing over with its homologue. The ring of duplicates could be restored to the chromatid by a crossover between the gene in the chromatid and one of the copies in the ring (Fig. 2 (e)-(h)). This mechanism is comparable with that proposed by Campbell<sup>18</sup> for attaching or detaching circular phage DNA from the DNA of its host.

The abnormal behaviour proposed for antibody genes in plasma cell precursors would require some modifications of the steps shown in Figs. 1 and 2 to allow for crossing over between any two copies (not necessarily the first and last as shown), and to accommodate matching

of the remaining copies to one of these two, wherever they were located in the series. The copies situated between those which had undergone mutual crossing over would be detached as a ring, and a second crossover, not necessarily between the same two copies, would be needed to restore them to the chromosome. If it is assumed that both chains of all the other copies of the antibody gene are matched against a copy which has taken part in an intrachromosomal crossover, this would mean that the antibody gene was now specialized to produce the one kind of polypeptide determined by this recombinant gene. The specificity would reside in the chromosome, and so it would be passed on at mitosis to daughter cells and would account for immunological memory and for the origin of a clone of cells all specifying the same polypeptide. The existence of a number of copies of the gene would allow a fast rate of synthesis of messenger RNA in each cell.

The main differences from normal in the two antibody genes would be that the copies of each would not be identical, and intrachromosomal crossing over would occur in particular somatic cells, the plasma cell precursors. The non-identity of the copies would seem to require no special adaptations, as long as matching of the copies of

Fig. 2. Diagram to show the postulated behaviour<sup>17</sup> at meiosis of a gene and sixteen copies of it. (a)-(d) Detachment of the sixteen copies as a result of intrachromatid crossing over between the first and last members of the series, leaving the master gene, *M*, in the chromatid in a position to undergo crossing over with a homologous chromatid from the other parent. (e)-(h) Reincorporation of the copies into the chromatid by crossing over. The lines and symbols have the same meaning as in Fig. 1. (B) Breakdown of unpaired chains; (S) synthesis. I suggest that in the structural genes for the antibody polypeptides in the plasma cell precursors, a similar intrachromosomal crossover takes place, but that it may occur between any two of the copies of the gene. I also suggest that the second intrachromosomal crossover, to reincorporate the copies detached by the first one, might involve different copies.

a gene occurs only when a gene is about to function, and the antibody genes do not function in the germ line. The mutations by which the copies of each antibody gene differed would presumably all be base substitutions or additions or deletions or three nucleotides or a multiple of three, because otherwise the reading of the remainder of the gene would be affected (see previously). These mutations would have accumulated during many generations under the influence of natural selection. The intrachromosomal crossing over in the antibody genes of the plasma cell precursors would need to be followed, as already indicated, by a slightly abnormal matching process.

The postulates for antibody variation would thus be slight alterations of normal processes. The consequences, however, would be profound, for each plasma cell precursor would acquire a unique genotype with regard to both of its antibody polypeptides. Even if the number of copies of an antibody gene was as small as sixteen (as in Figs. 1 and 2) many different genotypes for the plasma cell precursors would be possible if each of the sixteen differed by several base substitutions. This assumes that a crossover could occur between any two of the sixteen and that the hybrid DNA segments of the crossover could vary in length. Such variation is thought also to occur with normal crossing over. I assume that crossing over between copies would occur by essentially the same mechanism as normal crossing over between homologous chromatids at meiosis, and that correction of mispairing would occur in the hybrid DNA. That normal crossing over appears to be specific to structural genes and to be controlled in a way similar to transcription<sup>18</sup> implies that a mechanism for bringing about crossing over between copies of the antibody genes would be available.

It seems to be significant that the variation in antibody structure is almost entirely confined to the *N*-terminal part of each polypeptide. This would correspond to the part of the gene nearest to the operator. It seems likely that in normal crossing over dissociation of the DNA and chain synthesis are both initiated from the operator end of the gene<sup>19</sup>, and so these processes would have to extend only to the middle of the gene in the plasma cell crossovers. That antibody variability is in the *N*-terminal rather than the *C*-terminal parts of the polypeptide chains may therefore be an adaptation to minimize the length of DNA occupied by the crossover. There might be a selective advantage in minimizing the amount of DNA synthesis required, and in shortening the time taken for crossing over to occur.

If the structural gene for the light polypeptide chain of the antibody molecule and its counterpart in the homologous chromosome both underwent intrachromosomal crossing over and copy matching, each cell could produce two different polypeptides for the light chain, and by the same argument another two for the heavy chain. Possibly, however, each antibody gene is active in only one of the two homologous chromosomes.

Immunological tolerance would be accounted for by an antigen present early in development combining with the antibody produced by a particular plasma cell before that cell had divided after the hypothetical intrachromosomal crossing over. This antigen-antibody reaction would also have to destroy the cell. Conversely, an antigen-antibody reaction later in development would evidently stimulate the cell producing it to divide.

Further investigation of the variations in amino-acid sequence of antibody polypeptides will provide information relevant to the hypothesis. The variation in amino-acid sequence would be expected to correspond to different combinations of certain nucleotides at each position. For example, Doolittle<sup>4</sup> has found the alternatives shown in Table 1 (a) for the first six residues at the amino end of the light chains in the rabbit. The corresponding triplets of nucleotides in messenger RNA would be those shown in Table 1 (b)<sup>20</sup>. Recombinations would be expected to

Table 1. PREDICTIONS OF THE RECOMBINATION HYPOTHESIS

Position	1	2	3	4	5	6
(a) Amino-acids observed	Ala Ile Asp Glu	Val Leu	Val Leu Gln/Glu	Val Gln/Glu	Gln Ala	Gln Ala Thr

(d) Amino-acids predicted	Val Thr Asn Lys	—	—	—	Pro Glu	Pro Glu Lys

X = U, C, A or G.

(a) Data of Doolittle<sup>4</sup> for the first six residues at the amino end of the light chains in the rabbit. (b) The corresponding triplets in messenger RNA. (c) The minimum additional triplets expected to arise from recombination. (d) The amino-acid residues expected from (c). Ala, Asn, Asp, Gln, Glu, Ile, Leu, Lys, Pro, Thr and Val stand for alanine, asparagine, aspartic acid, glutamine, glutamic acid, isoleucine, leucine, lysine, proline, threonine and valine, respectively. A, C, G, U and X represent the ribonucleotides of adenine, cytosine, guanine, uracil and any of the bases, respectively, orientated with 5'-phosphates to the left.

give rise to at least to the additional triplets shown in Table 1 (c), and possibly to others depending on which of the alternatives in Table 1 (b) was present. The recombinant triplets in Table 1 (c) correspond to the amino-acids given at the bottom of the table. The finding of these amino-acid residues at these positions would therefore support the recombination hypothesis.

If the origin of antibody variability depends on somatic crossing over in the plasma cell precursors, as suggested, and if this crossing over requires DNA synthesis, it might be possible to detect this. Alternatively, it might be possible to inhibit the antibody variability by preventing the synthesis at the critical time.

I thank Professor H. G. Callan, Mr J. Hartley, Dr J. H. Renwick and Dr H. Subak-Sharpe for reading the manuscript.

Since this paper was submitted for publication, a mechanism has been suggested for the origin of antibody diversity which has several features in common with that proposed here<sup>21</sup>. The model differs from mine primarily in the three following respects. (a) The duplicate genes all have equal status (not a master and slaves) and hence are all liable to undergo crossing over with a homologue at meiosis. (b) The somatic crossing over is not intrachromosomal but is between either sister-chromatids or homologous chromosomes. (c) There is no matching of the copies against one of their number.

# Motivational Effects of Rewarding Intracranial Stimulation

by

D. BINDRA

J. F. CAMPBELL

Department of Psychology,  
McGill University, Montreal

The theoretical definition of behavioural reinforcers has proved to be a difficult problem. Experiments with rats now suggest that a feature common to reinforcers may be the ability to generate or condition incentive-motivational properties in a previously neutral stimulus.

In studies of behavioural patterns, reinforcers are usually defined in terms of their effects on the probability of occurrence of a response on which they are contingent. Thus when a stimulus event contingently paired with a response reliably increases its probability of occurrence, the stimulation is called a (positive) reinforcer or reward. The widespread acceptance of this definition seems to have created the impression that a change in response probability is the only important consequence of reinforcing stimulation; indeed, theoretical questions about the basis of reinforcement are at present discussed (for example, in textbooks<sup>1-3</sup>) exclusively in terms of the effects of reinforcers on response probability. Yet it is obvious that reinforcers also have motivational effects on behaviour. After being given a single small food pellet to eat, a hungry animal becomes agitated and everyone knows that the reinforcing stimulations of normal life (such as an unexpected compliment or insult) may change a man's mood and outlook on life for several hours, affecting his behaviour in a variety of situations. Such motivational effects may be important in understanding the mechanisms by which reinforcers increase response probability.

The question we set out to study was whether stimulation considered reinforcing by the response probability criterion has any measurable effect on aspects of behaviour that are not in any way contingently associated with the stimulation. We examined the immediate effects on general activity of electrical stimulation of "positive" and "neutral" brain sites in the same rats. We chose intracranial stimulation as the reinforcing agent because it appears not to depend on any response for the reinforcement to be completed; in contrast, the reinforcing effect of food, for example, depends on the animal making appropriate consummatory responses. In order to ensure that the reinforcing stimulation was independent of the response, each rat was habituated to the experimental situation and the reinforcing stimulation was turned on when it was sitting quietly. In order further to reduce the chance of accidental reinforcement of a response provoked by a prior stimulation, the stimulations were turned on only briefly and were separated by long intervals.

Two bipolar stimulating electrodes were stereotactically implanted in each of eight adult male rats under sodium pentobarbital anaesthesia. One of the electrodes was placed in the lateral hypothalamic "positive region" and the other in a "neutral region" of the cortex. The electrodes and the procedure of implantation used have been described by Valenstein *et al.*<sup>4</sup>. Histological examination showed that the reinforcing electrodes were located either in the medial forebrain bundle—lateral hypothalamic area at the level of the ventromedial nucleus—or in the ventromedial nucleus itself. The cortical electrodes were distributed along a 3 mm sagittal plane centred on the bregma and 2 mm lateral to the mid-line; two of these electrodes penetrated to the corpus callosum.

The properties of stimulations in the two regions were confirmed by testing the rats in a lever-pressing situation to determine whether they would press the lever to obtain hypothalamic or cortical stimulation. A 30 cm square box, about 50 cm high, was fitted with a lever; each press on the lever delivered a 0.5 sec train of biphasic pulses (pulse duration, 0.2 msec; frequency, 100 pulse pairs/sec; Grass 'SD-5' stimulator). All animals were

first tested with hypothalamic stimulation with a current of 0.8 m.amp. After four to six 30 min sessions, one on each day, the rate of lever pressing was determined for each rat in a 10 min test, which came at the end of the 30 min session. After this test, each lever-press produced cortical stimulation; in cases in which the stimulation led to squealing the amplitude was reduced to the minimum that yielded some observable response to stimulation (for example, sudden turning of the head). In the test with hypothalamic stimulation all animals pressed the lever at a moderate rate (mean rate 39/min), but all animals stopped pressing when the cortex was stimulated (mean rate 0/min). Though described here first, the lever-pressing tests were actually conducted after the tests measuring activity, so that the animals received no intracranial stimulation contingent on their response before the activity tests.

After recovery from surgery, the rats were habituated to an activity measuring box, 30 cm long, 20 cm wide and 28 cm high, with grey walls and a metal grid floor. When introduced into the box the animals explored a good deal but, after two or three 30 min habituation sessions, they mostly sat quietly. After this habituation, a series of sessions was begun to measure activity. A mirror was so arranged above the box that the experimenter could observe the rat from his chair. A micro-switch, connected to a 0.1 sec timer, was used by him to record the duration of perambulation; the experimenter pressed the microswitch for as long as the rat walked, reared or explored. (For details of this method, see ref. 5.)

Each of the activity measuring sessions started with a habituation period of 9 min, which was followed by two 6 min observation periods separated by a 1 min interval. A 0.5 sec train of biphasic pulses of the type described here was given at the midpoint of the observation period (after 3 min of the period). In the ten initial sessions, each animal was stimulated in the hypothalamic site on five sessions and in the cortical site on the remaining five sessions; four animals were stimulated first in the hypothalamic site, and the remaining four were stimulated first in the cortical site. In these sessions the level of current was 0.2 m.amp. After this, each rat was tested in seven additional sessions; in the first three of these the current level was set at 0.5 m.amp and in the last four at 0.8 m.amp. With stimulation at 0.5 m.amp, four of the rats were tested with hypothalamic stimulation and the remaining rats with cortical stimulation. With stimulation at 0.8 m.amp, all animals were tested with hypothalamic stimulation on two sessions and with cortical stimulation on two sessions, half the animals receiving each treatment first.

The mean proportion of time spent perambulating was calculated for each rat for each type of stimulation at each value of current; the number of cases represented in the mean varied between five and eight because some of the electrodes failed. The most striking finding was that a momentary (0.5 sec) stimulation had a prolonged effect on general activity. The most unexpected finding was that both cortical and hypothalamic stimulations produced about the same effects on general activity, and this was true at all three current levels (see Fig. 1). The animal would typically be sitting before stimulation and would start sniffing and moving around after the

Fig. 1. The left part of the figure shows the mean perambulation scores in 3 min pre- and post-stimulation periods at each of three levels of current applied at hypothalamic and cortical electrode placements. The two sets of bars on the right show the mean perambulation scores obtained during the tests of incentive-motivation, the two final conditioning tests (15 sec observation periods) and the two post-conditioning tests (1 min observation periods), with hypothalamic and cortical stimulation. The high pre-CS scores during the conditioning tests in the case of hypothalamic stimulation probably represent the effects of conditioning to the experimental situation as a whole.

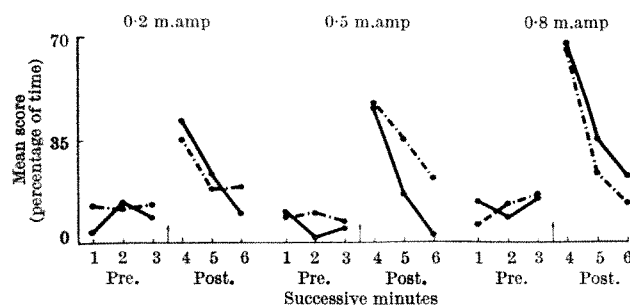

Fig. 2. Mean perambulation scores for the six successive 1 min sections of the activity tests conducted at each of three levels of current applied at hypothalamic and cortical electrode placements. The solid line represents hypothalamic stimulation and the broken line represents cortical stimulation.

stimulation. There were no obvious differences in the form of perambulation (for example, walking or rearing) after the two types of stimulation. The only notable difference was that cortical stimulation frequently produced squealing, suggesting that the stimulation was painful. The animals did not freeze or crouch, however, as is shown by their perambulation scores. The pre-stimulation and post-stimulation means of perambulation scores plotted over successive test sessions showed no evidence of habituation for either type of stimulation. Fig. 2 shows that the perambulation scores were highest in the first minute after stimulation, and then declined gradually, and this was true with both hypothalamic and cortical stimulations. Thus in spite of the marked differences between the reinforcing effects of hypothalamic and cortical stimulations, as measured by the lever-pressing test, the effects of the two on general activity were quite similar. Though differences in perambulation could certainly have been obtained by varying the parameters of stimulation, the point here is that differences in reinforcing value are not necessarily reflected in general activity.

In order to test the capacity of the two types of intracranial stimulation to generate conditioned incentive-motivational effects, a conditioned stimulus (metronome, 3 strokes/sec) was paired with intracranial stimulation. On each trial, the metronome was turned on 15 sec before the onset of intracranial stimulation, which consisted of five 0.5 sec stimulations set 1 sec apart; both the metronome and the stimulation were turned off simultaneously. The conditioning was carried on in the activity measuring box, and the activity of the animal was recorded for 15 sec before the onset of the metronome and then during the 15 sec metronome interval (before the onset of intracranial stimulation). All rats were first given seven sessions (four trials in each session) of this classical conditioning with hypothalamic stimulation. This was followed by two test sessions (without intracranial stimulation) in which activity was recorded during three 1 min observation periods; the metronome was sounded only during the middle period. All the animals were then given the same number of classical conditioning trials with cortical stimulation, and again this was followed by two test sessions. As seen in Fig. 1, the observations during conditioning, as well as the tests following the conditioning trials, showed that perambulation scores during the metronome periods were higher than during the adjoining control periods in the case of hypothalamic stimulation, but not in the case of cortical stimulation. Thus the metronome acquired conditioned incentive-motivational properties when it was paired with hypothalamic stimulation but not when it was paired with cortical stimulation. Not only was cortical stimulation incapable of generating incentive-motivational effects, it failed even to sustain them.

These experiments demonstrate under laboratory conditions that a positive reinforcing stimulation produces marked changes in behaviour even when the stimulation is not contingent on the prior occurrence of any particular response. Consistent with this demonstration is Miller's<sup>6</sup> proposal that a "go" or activating mechanism may act to intensify neural correlates of responses in progress and immediately preceding. One of his suggestions is that increased "overt motor activity" may serve to indicate the operation of the "go" mechanism. This particular suggestion is contradicted by the present finding that increased motor activity may occur as a result of non-reinforcing (cortical) stimulation as well. Enhancement of activity therefore cannot serve as a defining property of reinforcers.

Rather, our findings suggest that the capacity to generate (conditioned) incentive-motivational properties in an initially neutral stimulus may be a feature common to reinforcers. Certainly, the findings are consistent with the view that reinforcing stimuli, as well as the conditioned stimuli associated with them, create general neural states which have motivational properties that go far beyond the strengthening of particular stimulus-response connexions. That such neural states might also be created by natural reinforcers is indicated by the demonstration that a conditioned stimulus associated with the delivery of water to a thirsty animal raises the animal's level of general activity, and that the same stimulus associated with the delivery of a brief electric shock lowers the animal's level of general activity<sup>5</sup>. A systematic study of such reinforcer-induced motivational states may help to elucidate the neural basis of reinforcement.

## LETTERS TO THE EDITOR

## ASTRONOMY

## Role of Impurities in Interstellar Graphite Grains

ACCURATE measurements of the wavelength dependence of interstellar obscuration in the spectral range from 10,000 Å to 3400 Å (refs. 1-4) show a distinct change in the slope of the extinction curve at 4300 Å. Extinction observations have been made for a number of galactic regions, and it is found that a change in slope always occurs at 4300 Å but that the magnitude of the change differs significantly from one region to another. At the same time, an unidentified interstellar band of half-width approximately 20 Å appears at 4430 Å, but the discontinuity in the slope of the extinction curve does not affect the profile of this band<sup>5</sup>.

The precise shape of the extinction curve in the region of 4430 Å is being investigated by Harris (private communication) at a higher dispersion (120 Å/mm) than that used by Nandy<sup>2</sup> (1000 Å/mm). The preliminary results show that (1) the "knee" in the extinction curve near 4300 Å is real; (2) it is independent of the 4430 Å band; and (3) the extinction curve is best represented by two straight lines intersecting at about 4300 Å over the wavelength range considered (6000 Å-3400 Å), confirming the results of Nandy<sup>2</sup>.

Interstellar extinction in the ultra-violet deduced from rocket observations<sup>6-8</sup> shows a maximum at  $2330 \text{ Å} \pm 50 \text{ Å}$ . Fig. 1 shows the mean ultra-violet extinction points and the mean extinction curve obtained by Nandy<sup>2</sup> for a region in the direction of Cygnus for reference. The peak in the ultra-violet provides a strong argument in favour of the graphite model originally proposed by Cayrel and Schatzman<sup>9</sup> and Hoyle and Wickramasinghe<sup>10</sup>. The predicted energy difference between the states of the

Fig. 1. Interstellar extinction curve. The solid line denotes the extinction law for Cygnus (after Nandy<sup>2</sup>). ●, ×, ▲, Mean ultra-violet extinction points (●, Boggess and Borgmann<sup>2</sup>; ×, Stecher<sup>4</sup>; ▲, Smith<sup>5</sup>).

Fig. 2. Variation of absorption coefficient with wavelength (reproduced from Fuel (ref. 14)).

maximum density in the valence and conduction bands of graphite is close to 5 eV (ref. 11), which corresponds to a wavelength of 2480 Å, and the graphite peak indeed occurs in the neighbourhood of this predicted wavelength<sup>12,14</sup>. The observed "shoulder" of the extinction curve in the ultra-violet, however, is not sharp-peaked as is found for graphite. The purpose of this communication is to present some evidence that the knee of the extinction curve at 4300 Å may be produced by graphite particles containing small percentages of impurities.

The effect on its optical properties of impurities present in graphite can be investigated by examining the wavelength dependence of absorption coefficient and refractive index of coals. X-ray studies of high grade anthracites reveal that they are graphite-like and show three dimensional graphite crystallinity<sup>13</sup>. The variation of the absorption coefficient,  $k$ , and refractive index,  $n$ , with wavelength have been measured by Gilbert<sup>14</sup> for a series of coals of varying grades and for an artificial graphite in the spectral range from 6000 Å to 2400 Å. These studies have been made on coal in its bulk state, using a polarized light technique. The results show good general agreement with those of Ergun *et al.*<sup>12</sup>, who have measured the absorption of ultra-violet and visible light by coal and natural graphite in the form of flakes 500 Å-2000 Å thick.

The carbon content of the specimens used by Gilbert<sup>14</sup> varies from 81.5 per cent to 97 per cent for coals to 100 per cent for graphite. Spectral variations of the absorption coefficient and the real part of the refractive index are shown in Figs. 2 and 3. The absorption coefficient,  $k$ , is defined at a vacuum wavelength,  $\lambda$ , by  $I = I_0 \exp(-4\pi k x / \lambda)$ , where  $I_0$  is the intensity of the incident light, and  $I$  is the intensity of the emergent light after passing through a distance  $x$  in the medium. In Fig. 2, graphite shows a well defined absorption peak near 2500 Å. A peak also occurs for each sample, but it is not so well defined for high grade specimens. The  $n$  and  $k$  spectra of lower rank specimens run parallel to each other, but those of higher grade specimens depart from this trend. This is probably due to the fact that graphitization has not occurred in the lower grade specimens<sup>12</sup>. The shapes of the curves of wavelength dependence of  $n$  and  $k$  for specimens 36 and 15 (both high rank coals) behave very differently. Ergun *et al.*<sup>12</sup> have measured the extinction coefficient of sections 500 Å-2000 Å

thick of several grades of coals and natural graphite. The shapes of the curves of extinction coefficient versus wave energy (Fig. 4) for graphite and highest grade coals (anthracite and semi-anthracite) separate out from those for the lower grade ones, as found in Gilbert's  $n$  and  $k$  spectra of coals<sup>14</sup>. Also, like specimens 36 and 15 of Gilbert, the shapes for the anthracite and semi-anthracite are noticeably different in the blue-visible region. Ergun *et al.*<sup>12</sup> have reported that these high grade coals show X-ray scattering characteristic of two dimensional ( $hk$ ) graphite-like layers; and like graphite these coals show anomalous dispersion which is characteristic of a resonance phenomenon. Apparently, however, unlike crystalline graphite, they do not possess a well defined conduction band. Chemical analyses of these two coals show C, 92.4 per cent; H, 3.8 per cent; N, 0.5 per cent; O, 2.3 per cent; S, 1.0 per cent, for semi-anthracite, and for anthracite C, 94.1 per cent; H, 2.6 per cent; N, 0.4 per cent; O, 2.2 per cent; S, 0.7 per cent.

An interesting feature of the curve of absorption coefficient versus wavelength for specimen 15 (a high rank coal), shown in Fig. 2, is that a change in slope occurs near 4200 Å, which is close to the wavelength of the knee of the interstellar extinction curve. Such a change in slope also appears at about the same wavelength (4300 Å) for semi-anthracite in Fig. 4. This coincidence indicates that small amounts of impurities present in interstellar graphite particles can alter their optical properties so as to produce a change in slope of the interstellar extinction curve close to 4300 Å (see Fig. 1). It is our intention to examine whether the values of  $n$  and  $k$  for high grade coals like the specimen 15 of Gilbert<sup>14</sup> give a better fit to the observed interstellar extinction curve than the model of pure graphite covered with ice as used by Nandy and Wickramasinghe<sup>15</sup> to explain the Cygnus and Perseus extinction law.

Hoyle and Wickramasinghe<sup>10</sup>, and Donn *et al.*<sup>16</sup>, have examined in detail the growth mechanism of graphite grains in cool stars. They have concluded that crystalline graphite particles will condense in the photospheres of  $N$  stars and also in the outer atmospheres of ordinary  $M$  giants. These particles are ejected into interstellar space by radiation pressure, the critical radius for escape being of the order of  $10^{-5}$  cm. Impurity atoms can be incorporated in the grain structure in several ways. (1) If crystals grow at high supersaturation temperatures, some amount of foreign substances could be included in them. Furthermore, grains forming in the photospheres of  $N$  stars have to traverse stellar atmospheres before escaping; during this journey other substances could be adsorbed<sup>16</sup>.

Fig. 3. Variation of refractive index with wavelength (reproduced from *Fuel* (ref. 14)).

Fig. 4. Variation of extinction coefficient with wave energy (reproduced from *Fuel* (ref. 12)).

(2) During the encounters with clouds in interstellar space, energetic collisions between the grains may lead to melting and subsequent fusion incorporating other elements. (3) Sputtering can cause vacancies in the lattice, thereby enabling impurities to become incorporated more readily into the structure of the grain.

It is therefore highly improbable that interstellar graphite particles could exist in pure form. It is far more likely that these particles contain certain amounts of impurities. The observed knee at 4300 Å and the shoulder in the ultra-violet suggest that hydrogen and oxygen may be among the most abundant impurities, rendering the particles anthracitic. The variation in the amount and nature of these impurities may well explain the observed intrinsic scatter in the extinction curves.

We thank L. A. Gilbert of the BBC, London, for drawing our attention to his work on graphite and certain specimens of coals<sup>14</sup>.

## PLANETARY SCIENCE

## The Goose Lake Meteorite and the Goose Lake Fragments

THE metallographic structure of the main mass of the Goose Lake meteorite has been described by Henderson and Perry<sup>1</sup>. The meteorite was discovered in the autumn of 1938 and was removed from the site in May 1939. The site was re-examined in 1960, when a large number of small, partly corroded, fragments were discovered in and around the place from which the main mass had been removed. The circumstances under which the fragments were found, together with a preliminary description of their structure and some suggestions about their origin, can be found in ref. 2.

We have examined a number of typical fragments weighing 0.2–0.4 g which were made available to us by Dr C. P. Butler and we have also examined the 72 g slice of Goose Lake [B.M. 1959, 951] which was made available to us by Dr Hey of the British Museum (Natural History).

The slice [B.M. 1959, 951] appears to have suffered distortion of the surface layers all round the smooth outside surface of the meteorite and this distortion extends inwards to a depth of about 0.5 mm. At a number of places within the distorted layer there appear to be relics of kamacite granulation, but the patches of granulation extend only to a depth of 0.1–0.2 mm below the present outer surface of the meteorite. The granular patches may be the relics of a heat alteration zone which was produced during atmospheric flight, in which case the zone of kamacite granulation has been almost completely removed by subsequent terrestrial corrosion and/or abrasion. In this context one source of terrestrial damage which must not be overlooked is the surface deformation which may arise when a heavy mass of iron is hauled about by chains during the recovery process.

In [B.M. 1959, 951] two small areas of non-metallic phase were present. The smaller was situated about 3 mm below the present surface of the meteorite and the larger was nearby but situated about 12 mm below the surface. Each consisted of schreibersite with swathing cohenite, and, as is shown in Fig. 1, the cohenite has undergone partial decomposition into graphite and ferrite at places where the cohenite was cracked. Furthermore, the range of plessite structures encountered within the slice included the spheroidal form which was figured by Henderson and Perry<sup>1</sup>, but more usually the large fields of plessite showed

Fig. 1. Schreibersite surrounded by cohenite in [B.M. 1959, 951] ( $\times c. 75$ ). Etched in alkaline sodium picrate reagent. The schreibersite shows grey with cracks and holes (black); the cohenite has stained dark but shows unstained ferrite and black graphite along the radial cracks. The matrix is kamacite (smooth grey).

Fig. 2. An example of the complex decomposition morphology of plessite in the Goose Lake meteorite [B.M. 1959, 951] ( $\times c. 55$ ). Etched 2 per cent 'Nital'.

Fig. 3. Example of mechanically deformed fine pearlitic plessite from fragment (GLF)1 ( $\times c. 290$ ). Etched 2 per cent 'Nital'.

complex structures with comb-like, spindle, bainitic and fine pearlitic plessites coexisting to a greater or less extent as is shown in Fig. 2. Our own observations on the Canyon Diablo meteorite<sup>3</sup> suggest that fine pearlitic plessite is usually found in the vicinity of cohenite. The main kamacite bands of Goose Lake contained occasional rhabdites.

The Goose Lake fragments (GLF) are always corroded to a greater or less extent and seven of the least corroded fragments were examined metallographically. In no fragment was unambiguous granulation of the kamacite visible, but they all showed a greater or less degree of mechanical distortion of the type reported by Butler<sup>2</sup>. Moreover, mechanically distorted versions of all the types of structure noted above for the main Goose Lake mass have been found in the fragments. For instance, Fig. 3 shows a distorted area of fine pearlitic plessite in (GLF)1, while Fig. 4 shows cohenite in (GLF)12, and in the same fragment an earlier generation of relatively large hexagonal nodules of graphite was found embedded in the kamacite out of contact with the cohenite. A similar graphite nodule from (GLF)6 is shown in Fig. 5.

Fig. 4. Decomposed cohenite in fragment (GLF)12 ( $\times c. 290$ ). Etched in alkaline sodium picrate reagent. Undecomposed cohenite is stained dark. At cracks in the cohenite the compound has decomposed into black graphite and light polycrystalline ferrite. Some grey corrosion product is present at the interface between cohenite and the kamacite matrix (right side of photograph).

Fig. 5. Hexagonal nodule of graphite embedded in kamacite in fragment (GLF)6 ( $\times 500$ ). Polarized light.

From this examination it would appear that the structure of the Goose Lake fragments is not inconsistent with the structure of the main Goose Lake mass. Where there are differences they are differences of amount rather than of character. For instance, in the fragments the decomposition of cohenite to graphite and ferrite seems to be slightly more complete than is the case with the two examples of cohenite which are present near the surface of [B.M. 1959, 951] and, furthermore, while the presence of carbon shows itself as cohenite in the slice it is made manifest in some of the fragments by the appearance of both cohenite and nodular graphite. Thus some of the Goose Lake fragments appear to have arisen from carbon rich areas of the main Goose Lake mass, but it remains an open question where those areas of carbon enrichment were located in relation to the size and shape of the present Goose Lake meteorite and how they came to be distributed about the main mass at its place of discovery.

## Large Surface Carbon Dioxide Anomalies in the North Pacific Ocean

DURING the trans-Pacific Lusiad expedition of R.V. Argo, May 18–June 9, 1962, Waterman observed a large inequality of the partial pressure of the carbon dioxide in the atmosphere and in the surface water in the centre of the North Pacific Ocean<sup>1</sup>. His traverse (Fig. 1) showed that the partial pressure of carbon dioxide ( $P_{CO_2}$ ) in the water was generally less than that in the atmosphere (320 p.p.m.), with a maximum anomaly of about 20 per cent. This difference in  $P_{CO_2}$  is too large to be accounted for solely by changes in temperature, salinity, or solution of calcium carbonate<sup>2</sup>. Our recent work shows that the carbon dioxide anomaly is of biological origin. It is similar to, but of greater dimensions than, the biologically induced carbon dioxide anomalies found by Teal and Kanwisher<sup>3</sup>.

Fig. 1. Early summer  $P_{CO_2}$  contours in the North Pacific. Solid lines show the cruise tracks of R.V. Argo and R.V. Yaquina. The arrows indicate the general surface circulation pattern. Subarctic boundary, indicated by a dotted line, separates the ocean into the subarctic (north) and the subtropic (south) regions. Chlorophyll *a* histogram on the Yaquina traverse was prepared from average values per 2 latitudinal degrees: its concentration is in  $mg/m^3$ .

In June 1966, we studied the surface chemical conditions of the ocean along the Hawaiian–Aleutian line aboard R.V. Yaquina of Oregon State University<sup>4</sup>. From the surface pH, alkalinity, salinity, and temperature data, we calculated  $P_{CO_2}$  in sea water for our traverse<sup>5</sup>. Although the pH-alkalinity method for calculating  $P_{CO_2}$  in sea water enables us to estimate only in intervals of 10 p.p.m., we found a good agreement between the Argo and the Yaquina results where the traverses crossed each other. The summer (June) contours of  $P_{CO_2}$  based on these two traverses were plotted (Fig. 1). These contours follow the general surface circulation pattern of the North Pacific, as shown by arrows in Fig. 1.

A good correlation between the  $P_{CO_2}$  and the amount of chlorophyll *a* in the surface 1 m was observed in the Yaquina data. (The details of the analytical method used to measure chlorophyll *a* are given in ref. 5. In order to take into consideration variations in diel pigment, we have averaged the values for pigment over two latitudinal degrees to give the pigment distributions shown in Fig. 1.) The maximum pigment concentration of 1.5  $mg/m^3$  occurred at the minimum  $P_{CO_2}$ . The pigment concentration decreased with the increase in the partial pressure. The plant nutrient concentrations were quite low where  $P_{CO_2}$  was less than 260 p.p.m.: phosphate range was 0.2–0.5  $\mu moles/l.$ , nitrate 1–4  $\mu moles/l.$ , silicate 3  $\mu moles/l.$  It is probable that a phytoplankton bloom increased the pigment content and decreased nutrients in sea water. It is also possible that the organic matter production by phytoplankton lowered  $P_{CO_2}$  in the surface water, and maintained it by kinetically slow reactions involving the production and consumption of organic acids and bases.

The surface chemical conditions of oceanic water are quite different even from that 1 m below the surface.

Goering and Menzel<sup>6</sup> showed that dissolved organic carbon in the upper 3 mm of water was 0.4 mg/l. more than that at a depth of 1 m in the tropical Atlantic. This was attributed to the accumulation of decomposing organic material floating up to the surface. The increase in organic carbon indicates the possibility of increasing organic acid and base contents at the surface, which in turn affect  $P_{CO_2}$ , for the physical properties of the air-water interface may be extensively modified by the adsorption of surface active organic matter at the sea surface<sup>7</sup>. Because the air-sea exchange of carbon dioxide has to pass through this surprisingly different chemical "membrane" at the sea surface, we feel that a sustained anomaly of  $P_{CO_2}$  across the interface can be maintained biochemically.

We propose that the high anomaly in  $P_{CO_2}$  in the North Pacific surface water is produced by the combined effect of general oceanic circulation, biomass production and consumption. The organic matter could have been brought toward the area of low  $P_{CO_2}$  by the surface currents, and perhaps it is slowly utilized there by biomass. There is, however, reason to believe that the production of phytoplankton in the anomaly area was recent and may have been *in situ* rather than advected. Ratios of chlorophyll *a* to  $\beta$  carotene had maxima in the area of the high anomaly as well as near the Hawaiian and Aleutian Islands. High pigment ratios indicate a "healthy" population<sup>8</sup>. A population produced elsewhere and advected towards a convergence could be senile and the ratios may be low.

The carbon dioxide anomaly that Waterman<sup>1</sup> and we observed could be a seasonal rather than a permanent phenomenon, for we both made our observations in early summer. We believe that winter observations could show whether the anomaly is a seasonal or permanent phenomenon. We plan to study the winter condition in 1968.

We thank Professor S. J. Neshyba and A. Marmelstein for their field assistance. This work was supported by grants from the US National Science Foundation and the US Department of the Interior.

### Alkali Olivine Basalt dredged near St. Paul's Rocks, Mid-Atlantic Ridge

RECENT studies of deep sea basalts have revealed the great predominance of olivine tholeiites over both normative nepheline and normative quartz basalts<sup>1</sup>. An alkali basalt recently dredged between 2,950 and 1,975 m near St. Peter and St. Paul Rocks (St. Paul's Rocks) consequently seemed worthy of prompt description. Although mentioned in an abstract<sup>2</sup>, we have not previously published a chemical analysis of this basalt. This alkali basalt flow is of special interest because it is not part of a large submarine volcano, but rather evidently was erupted directly on a floor of spinel peridotite mylonites similar

to and contiguous with those described from St. Paul's Rocks, a probable high temperature intrusion derived from the mantle<sup>3</sup>.

Extensive dredging was carried out around St. Paul's Rocks during cruise 20 of the R.V. Atlantis II of the Woods Hole Oceanographic Institution in an attempt to delineate the outcrop of the ultrabasic mylonites which are exposed on the islets. Numerous rock types, in addition to the mylonites, were dredged within sight of the islets; although their study is not yet complete, some of the more interesting have been examined in the laboratory, and a detailed report is in preparation.

One of the most remarkable rock types, the subject of this report, is a vesicular basalt containing abundant small olivine nodules and partly "digested" mylonitized spinel peridotite inclusions. The dredge (No. 43) from which this basalt was obtained is located on Fig. 1.

Fig. 1. Bathymetry and location of dredge A II-20, 43, St. Paul's Rocks.

The ultramafic intrusion exposed at St. Paul's Rocks extends beneath the sea along a ridge elongated in an E.N.E. direction. Dredge samples indicate that the submarine exposures of the intrusion are spinel peridotite mylonites and alkaline ultrabasic brown hornblende mylonites, the two major rock types on the islets<sup>3</sup>. A complex series of rocks which includes fresh and metamorphosed basalts, basaltic pyroclastic rocks, basic and ultrabasic plutonic rocks, and carbonate sedimentary rocks outcrop to the north and south of the intrusive mass. Some of the dredges, even those which only covered a short distance of the bottom, yielded a wide variety of rocks, suggesting that the rocks probably dip steeply around the margin of the intrusion. The alkali basalt described here probably occurs unconformably on the

intrusion, and is probably much younger than the commonly deformed and altered rocks which rim the intrusion. A large amount of talus derived from the islet was in the dredge on top of the alkali basalt fragments; evidently this talus was the last material to enter the dredge.

Table 1 gives the bulk analysis of a sample from which the nodules were extracted after coarse crushing. The basalt is perfectly fresh in hand specimen and in thin section. To remove any possible salt contamination, the sample was washed in distilled water after fine grinding. The high titania, soda and potash, and the low silica, are particularly significant in the analysis. These features, and the presence of nepheline in the norm, clearly place the basalt in the alkali olivine basalt series. Deep sea basalts may have "alkaline affinities"<sup>1</sup>, and may contain abundant normative and modal olivine, but rarely contain normative nepheline in the amount recorded here. The high barium (300 p.p.m.), strontium (500 p.p.m.) and zirconium (200 p.p.m.) further confirm the alkaline nature of this basalt, although the high nickel (270 p.p.m.) and chromium (250 p.p.m.) are anomalous for alkali basalts.

Table 1. COMPOSITION OF ALKALI OLIVINE BASALT\*, 4 II-20, 43-49, DREDGED A FEW KILOMETRES NORTH-EAST OF ST. PAUL'S ROCKS

		Norm	
SiO <sub>2</sub>	43.15	Or	9.63

H <sub>2</sub> O +	1.21		
H <sub>2</sub> O -	0.15		98.61
TiO <sub>2</sub>	2.70		
P <sub>2</sub> O <sub>5</sub>	0.75		
99.97		Analyst: E. Jarosewich	

\* The analysed basalt is extremely fine grained and contains olivine phenocrysts in a matrix of microlites of plagioclase (about An<sub>60</sub>), titan-augite, olivine and light brown barkevikitic hornblende. Accessories include an iron-titanium oxide, biotite, apatite and possibly haüyne. Small amounts of clear glass and alkali feldspar also occur. Modal nepheline is not present.

The predominance of low potash tholeiitic basalt on the ocean floor and the apparent restriction of alkali basalts to the top of high volcanic edifices has been noted by Engel *et al.*<sup>2</sup>. In the Hawaiian Islands, alkali basalts occur mainly as late, quantitatively minor extrusives. These relationships led some petrologists<sup>3</sup> to postulate, first, that alkali basalts are derived by low pressure differentiation of sub-alkaline olivine basalts of the "oceanic tholeiite" type in near surface magma chambers, and second, that "oceanic tholeiite" magma is the only basaltic magma derived from the mantle. Experimental data indicate that low pressure differentiation of tholeiitic magma should not yield normative nepheline liquids<sup>4</sup>, and thus argue against the first view.

The alkali basalt described here also suggests mantle derivation of alkali basalts. The basalt is clearly not part of a thick "oceanic tholeiite" pile (Fig. 1), and thus based on field occurrence alone is an unlikely low pressure differentiation of "oceanic tholeiites". It would appear that "parental" alkali basalt magma originates by some other, more deep-seated phenomena, such as partial fusion of eclogite of tholeiitic basalt composition—a process outlined by Yoder and Tilley<sup>5</sup>.

The St. Paul's Rocks situation clearly indicates that it is not always true that oceanic alkaline basalts occur as late eruptives in otherwise tholeiitic sequences. Thus caution should be used in tying the origin of all oceanic alkaline basalts to the situation exemplified, for example, by the Hawaiian Islands.

## PHYSICS

### Identification of High Gain Laser Lines in Argon

BRISBANE has reported three high gain laser lines in a pulsed discharge in argon<sup>1</sup>.

The first line at 1.270  $\mu$ m is explained in Paschen notation as the transition  $3d_2-2p_6$ , which has the wavelength 12,638-480 Å (ref. 2). We believe that the observed line is the same that we have reported earlier<sup>3</sup> as a super-radiant line with the wavelength 12,702.21 Å. It corresponds to the transition  $3d'[1\frac{1}{2}]_1 \rightarrow 4p'[1\frac{1}{2}]_1$  in Racah notation ( $3s'_1 \rightarrow 2p_2$  in Paschen notation) and the wavelength in spontaneous emission is 12,702.280 Å (ref. 2).

The second line at 1.793  $\mu$ m is explained as the transition  $3d_5-2p_6$ , which has the wavelength 17,914.726 Å (ref. 2). It could also be explained as the transition  $3d_6-2p_7$  with the wavelength 17,914.629 Å (ref. 2) as pointed out by Patel *et al.*<sup>4</sup>, who observed the line in a CW operated laser.

### Validity of the Debye Scattering Equation in Elastic Electron Diffraction

THE methods of Debye<sup>1</sup> are accepted in the scattering of electrons by gases, but despite the application to thin films by Germer and White<sup>2</sup> their use in kinematic electron diffraction from polycrystalline solids has seemed suspect and none of the recent texts on electron diffraction mention the methods. Possibly this is because of a pre-occupation with dynamical theory. Many real specimens, however, diffract kinematically and the Debye "gas" equation, if valid for closely packed small crystals, would enable the detailed intensity profile for polycrystalline films to be computed. The objection to the Debye theory is that it neglects interference between atoms situated in different crystals; while this is permissible for a gas of large molecules, it requires justification if the molecules (or small crystals) are densely packed.

The work of Menke<sup>3,4</sup> on molecular liquids in fact shows that the Debye gas equation must be valid for polycrystalline solids scattering X-rays kinematically. But the methods must be adapted if they are to be applied to electron radiation, for electron waves have a small coherence width  $2R_c$  of about 1000 Å, and the specimens are thin disks, perhaps 100 Å thick and 1 mm in diameter. Thus any one coherently irradiated volume will contain too few crystals for statistical methods to be valid. The specimen is, however, an assembly of about  $10^8$  of such volumes. One may therefore invent a "statistical coherence zone" having the properties of the coherently irradiated specimen volumes averaged over the assembly. To obtain the elastically diffracted intensity one must average phase factors between pairs of crystal centroids weighted by the probability of the occurrence of a given centroid-to-centroid spacing. This averaging can be carried out for a statistical coherence zone because it can contain very many points accessible to the crystal centroids.

Consider a disk shaped statistical volume of coherence containing  $N_c$  crystals, each of which is assumed to be similar and to possess  $n$  atoms. One may follow the X-ray procedure<sup>4</sup> and show that the theoretical elastic electron intensity is proportional to three terms. One of these depends on internal interference effects only

$$I_1 = nN_c f^2 \left( 1 + \frac{2}{n} \sum \frac{\sin 2\pi s r_{pq}}{2\pi s r_{pq}} \right) \quad (1)$$

It is the Debye gas equation,  $s = 2 \sin \frac{1}{2}\beta/\lambda$ .

The other two terms result from interference between atoms in different crystals. An approximation to one of them is

$$I_2 = -8f^2(N_c - 1)\Psi\Phi(2\pi s D) \quad (2)$$

where

$$\Phi(u) = 3(\sin u - u \cos u)u^{-3}, \Psi^{\dagger} = \sum \frac{\sin 2\pi s r_{cp}}{2\pi s r_{cp}}$$

and  $D$  is rather greater than the diameter of a crystal. The summation  $\Psi^{\dagger}$  is over every centroid-to-atom spacing in a crystal. The third term is a "Debye volume interference" term and contains a factor

$$I_3 = 4f^2 N_c(N_c - 1) \Psi \left\{ \frac{J_1(v)}{v} \right\}^2 \quad (3)$$

where  $v = 2\pi s R_c \cos \frac{1}{2}\beta$ , and  $J_1(v)$  is the first order Bessel function.

$I_1$ ,  $I_2$  and  $I_3$  all contribute to an intense maximum at the origin;  $I_2$  has a second weak maximum when  $s \approx 0.91 D^{-1}$ , and  $I_3$  when  $s \approx 0.82 R_c^{-1}$ . For example, if  $D = 50$  Å (small crystals and kinematic conditions) and  $R_c = 500$  Å, these weak maxima occur at  $s = 0.018$  and  $s = 0.0016$  Å<sup>-1</sup> respectively. For comparison the first maximum of the diffraction pattern of face centred cubic metals occurs at values of  $s$  greater than  $0.3$  Å<sup>-1</sup>.

In a real film there must be a spread of shapes and sizes which will add mathematical complexity without altering the physical principles. The remarkable and important fact is that the intercrystal interference effects do not contribute to the normal elastic electron diffraction pattern and therefore that the Debye equation (1) is valid for computing the elastic intensity profile in kinematic diffraction of electrons by polycrystalline solids.

## Relationship between Wettability and Adhesion of Polyethylene

THE formation of a good adhesive joint requires intimate contact between the substrate and the adhesive. This requirement implies that at some point in the cure of a bonded joint the adhesive must become a liquid so that this contact can be obtained. Such contact can be termed the wetting of the substrate by the adhesive, depending on the relative roughness of the substrate<sup>1</sup>.

Wetting of a surface by a liquid is formally defined by the well known Young equation (equation (1))

$$\gamma_{sv} - \gamma_{sl} = \gamma_{lv} \cos \theta \quad (1)$$

where  $\gamma_{lv}$  is the surface tension at liquid-vapour interface;  $\gamma_{sl}$ , the surface tension at solid-liquid interface;  $\gamma_{sv}$ , the surface tension at solid-vapour interface; and  $\theta$  is the contact angle.

The relationship between bond strength and wetting can be found if one considers the reversible work of adhesion  $W$  needed to separate a liquid from a solid surface.  $W$  is given by an energy difference equation as follows

$$W = \gamma_{sv} + \gamma_{lv} - \gamma_{sl} \quad (2)$$

Combining equations (1) and (2) gives

$$W = \gamma_{lv} (1 + \cos \theta) \quad (3)$$

Because  $\gamma_{lv}$  is always positive, the theory predicts a direct linear relationship between bond strength and  $(1 + \cos \theta)$ .

The angle  $\theta$  is a measure of the degree of wetting and can be determined using a contact angle goniometer or, in the case of very small  $\theta$ , interferometry. Laboratory methods for obtaining  $\gamma_{lv}$  are well defined and no problems should be encountered in using methods involving the Du Nouy ring tensiometer. With  $\gamma_{sl}$  and  $\gamma_{sv}$ , accurate measurement is impossible. Zisman<sup>2</sup> has introduced  $\gamma_c$  (critical surface tension of a solid). This empirically determined parameter is a useful characterization of the surface in so far as it is proportional to  $\gamma_s$  (specific surface free energy of the solid). It will be seen from the definition of  $\gamma_c$  that it is a determination of the left side of equation (1) corresponding to  $\cos \theta = 1$  (complete wetting). Thus knowing  $\gamma_c$  eliminates the need to know  $\gamma_{sv} - \gamma_{sl}$  in order to find the value of  $\gamma_{lv}$  corresponding to complete wetting. Correspondingly  $\gamma_c$  can be used to predict lesser degrees of wetting. In brief, the method involved in a determination of  $\gamma_c$  for a solid is as follows. Using a set of liquids of varying surface tension (preferably a homologous series of organic liquids, for example,  $n$ -alkanes) contact angle measurements are taken on the surface in question. A plot of  $\cos \theta$  against the liquid surface tension,  $\gamma_{lv}$ , will reveal a straight line relationship. If extrapolated to  $\cos \theta = 1$  (which represents complete wetting) this graph will yield  $\gamma_c$  as the value of liquid surface tension at the point where the plot crosses the line  $\cos \theta = 1$ . In other words, liquids whose surface tensions are greater than  $\gamma_c$  will not give complete wetting on the surface, while liquids with surface tensions less than or equal to  $\gamma_c$  will give complete wetting.

The critical surface tension  $\gamma_c$  now makes available a method for classifying surfaces as far as their energy availability is concerned. Zisman has shown the value of  $\gamma_c$  for clean polyethylene to be about 31 dynes/cm. Thus polyethylene is a low energy surface in comparison with metals or glass, which have considerably higher values of  $\gamma_c$ . This difference in surface energy availability indeed makes it more difficult to bond to polyethylene than to metal. Polytetrafluoroethylene is reported to have a  $\gamma_c$  of about 18 dynes/cm, corresponding to the non-sticking property of "Teflon".

Any contamination on the surface will in general lower the value of  $\gamma_c$  apparent at the surface, and surface pre-

paration before taking wetting measurements or bonding is therefore recommended in order to increase the surface energy available.

The question of whether an increase in wetting will give a proportional increase in bond strength was investigated for the case of polyethylene. The most direct approach to such a problem would be to limit the number of variables to a minimum by using only one type of substrate material and one adhesive, and attempting to keep all other conditions as constant as possible. The only variable used to influence the wetting was the type of surface treatment given the polyethylene<sup>3</sup>.  $\gamma_{LV}$  was therefore kept constant while  $\gamma_c$  was varied.

We used specimens of low density polyethylene measuring 1 in.  $\times$  4 in.  $\times$   $\frac{1}{8}$  in. The treatments given are shown in Table 1. The adhesive used was a mixture of a bisphenol type epoxy and a liquid polyamide resin in a 70/30 ratio by weight. This adhesive has a surface tension of 41.7 dynes/cm.

Table 1 gives the results obtained in measuring the contact angles formed by the adhesive on the polyethylene surfaces prepared by various means. The average value of contact angle at the bottom of each column decreased as the polyethylene was given better surface treatments. This indicates that the value of  $\gamma_c$  for the polyethylene was being increased by the treatments. Variation in the contact angles in any one column is evidence of inhomogeneity of the surface and/or the adhesive. The best wetting obtainable was about 18°, as is shown in the last column of Table 1. This is consistent with the theory because the adhesive surface tension is 41.7 dynes/cm, while the value of  $\gamma_c$  for polyethylene is 31 dynes/cm. Under no condition should such a system give complete wetting.

Fig. 1. Plot of bond strength against  $(1 + \cos \theta)$  on polyethylene using epoxy-polyamide adhesive in 70/30 ratio by weight.

Shear specimens with a bonded area of 1 in.  $\times$   $\frac{1}{2}$  in. were prepared from the different polyethylene surfaces. Once cured the samples were ruptured. The results are given in Fig. 1. The points on the plot represent the different types of treatment shown in Table 1. The experimental results agree excellently with the theory because they show bond strength and  $(1 + \cos \theta)$  to be linearly related with a positive slope. Such a plot would be useful in determining the strength values of bonds without having to destroy them.

It must be remembered that contact angles are influenced only by the surface. Any weak boundary layers beneath the surface would not contribute to the contact angle. Any break in such a region could not therefore be related to contact angles. Breaks occurring because of cohesive failure of the adhesive would also be irrelevant to surface energetics and therefore must also be avoided. If, however, one eliminates any weak boundary layer or has evidence that the break is adhesional (to the unaided eye) between the adhesive and the surface, as was the case with all the samples tested, then a plot similar to Fig. 1 can be obtained.

## THE SOLID STATE

### Structure of High Modulus Carbon Fibres

In a recent letter we drew attention to the fact that carbon fibres with a range of mechanical properties<sup>1</sup> could be produced by a method developed at the Royal Aircraft Establishment<sup>2</sup>. These fibres are made from an oriented textile fibre and there is no evidence to suggest that the carbon fibres are sensitive to surface damage like glass fibres. Tensile fracture was tentatively attributed to internal flaws. This letter reports some observations of the structure made on thin sections cut from fibres.

The fibres were sectioned, after mounting in an acrylic resin, on an L.K.B. 'Ultratome 1', with a Leitz diamond knife, at a cutting speed of 1 mm/sec. Longitudinal sections 300 Å thick or less were cut.

Fig. 1 shows a longitudinal section of a fibre with a Young's modulus of  $60 \times 10^6$  lb./in.<sup>2</sup> after heating to 2,500° C. An internal structure of long narrow units lying parallel to the fibre axis can be seen. These units are about 100 Å across, but their length is difficult to define. The electron diffraction pattern (Fig. 2) shows the high degree of preferred orientation in which layer planes, indicated by the (002) reflexion, lie parallel to the fibre axis.

X-ray diffraction has shown that the crystallites are turbostratic with  $L_c$  at least twelve layer planes and  $L_a$  in the range 60–120 Å (R. J. Seed and J. N. Eastabrook, personal communication).

Sections were cut from fibres that had been carbonized to 1,000° C only. While being cut and collected these sections invariably ruptured along their length and opened to give the net-like structure shown in Fig. 3. The fibril units forming this network are about 800–1000 Å across and appear to run the full length of the section with no apparent terminations. From X-ray diffraction  $L_a$  in this 1,000° C material is about 30 Å. The net-like structure is perhaps a fundamental structure in carbon fibres because similar sections can be prepared from fibres heated to

2,500° C if attempts are made to cut thin sections less than 200 Å thick.

Thus from these sections the carbon fibres are seen to consist of long primary units lying parallel to the fibre axis and these primary units are bonded together to form a stretched network of branched fibrils that apparently run the full length of the fibre. The size and degree of branching of the fibrils may be derived from the fibril structure of the parent fibre.

In Fig. 4 a thin section of a high temperature fibre that was broken while being collected is shown. The irregular path of the fracture suggests a crack deflexion mechanism. The fracture behaviour of a fibre may be influenced by the size of fibrils and how well they are bonded together.

Bacon and Tang<sup>3</sup> have found long primary structures in carbon fibres made from oriented rayon fibres, and because the precursor fibre used here was not cellulosic it appears that the structure of the carbon fibres is a consequence of the structure of the parent organic fibre regardless of chemical constitution. We think that the modulus of the carbon fibre is determined by the orientation of the graphite crystallites within the carbon fibrils while the strength is a function of the inter-fibrillar bonding.

Other physical properties of the fibres of technological importance are a result of the orientation and small crystallite size. Because the crystallites are highly oriented, and the crystallite size, Young's modulus and density of the fibres are known, the thermal conductivity may be estimated, because graphite is a lattice conductor. The Debye equation can be used, namely  $K = \frac{1}{3} \rho C v l$

Fig. 1. Longitudinal section of a fibre. Young's modulus  $60 \times 10^6$  lb./in.<sup>2</sup>.

Fig. 2. Electron diffraction pattern of the fibre shown in Fig. 1.

Fig. 3. Longitudinal section of a fibre carbonized to 1,000° C. The section has opened to give a net-like structure.

Fig. 4. Longitudinal section, of a high modulus fibre, broken while being collected.

where  $K$  = thermal conductivity,  $\rho$  = density,  $C$  = specific heat for unit mass,  $v$  = velocity of lattice waves transporting the thermal energy, and  $l$  = the mean free path for scattering of these waves. Taking the mean free path as equal to the  $L_a$ , that is, 100 Å, and calculating  $v$  from  $E$  and  $\rho$  gives a value for  $K$  of  $0.142 \text{ cal cm}^{-1} \text{ sec}^{-1} \text{ }^\circ\text{C}^{-1}$ . This is in reasonable agreement with the value calculated from measurements of the thermal conductivity of a composite bar at 77° C of 0.34 vol. fraction unidirectional fibres in a plastic matrix, that is,  $0.12 \text{ cal cm}^{-1} \text{ sec}^{-1} \text{ }^\circ\text{C}^{-1}$  (P. H. H. Bishop and L. N. Phillips, personal communication). This value is much lower than the thermal conductivity of a heat treated pyrolytic graphite (for example,  $3.4 \text{ cal cm}^{-1} \text{ sec}^{-1} \text{ }^\circ\text{C}^{-1}$  at 40° C (ref. 4)) and clearly shows the effect of crystallite size.

The same is true of the electrical resistivity which is  $3 \times 10^{-4} \text{ ohm cm}$  at room temperature for fibres of Young's modulus  $60 \times 10^6 \text{ lb./in.}^2$  whereas highly ordered pyrolytic graphite has a resistivity of about  $4 \times 10^{-5} \text{ ohm cm}$  parallel to the basal planes<sup>5</sup>.

Our observations on the structure of the carbon fibres are in agreement with those of D. V. Badami, J. C. Joiner and G. A. Jones which are published below.

### Microstructure of High Strength, High Modulus Carbon Fibres

Watt, Phillips and Johnson<sup>1</sup> have reported the development of high strength, high modulus carbon fibres. More recently, Moreton, Watt and Johnson<sup>2</sup> have reported the variation of the tensile properties of these fibres with their heat treatment temperature. Shindo<sup>3</sup> did pioneer work on this class of fibre, including X-ray and electron diffraction and transmission electron microscopy on broken fragments, but he gave no clear picture of the structure within the fibre. This communication reports the results of our initial structural studies of fibres prepared by a similar process to that of Watt, Phillips and Johnson. These fibres, with diameters in the range 6–8  $\mu$ , had been heat treated to 2,600°C and had moduli of  $60 \times 10^6$  lb./in.<sup>2</sup> and ultimate tensile strengths of  $0.25 \times 10^6$  lb./in.<sup>2</sup>.

X-ray diffraction photographs (Fig. 1) taken of bundles of these fibres suggest that they consist of graphite crystallites about 50 Å in size—calculated from the line breadth of the (002) reflexion using the Scherrer equation—and that the basal planes are highly oriented along the fibre axis, with a spread of about  $\pm 10^\circ$ . A relation between orientation and modulus has been found which is similar to that reported by Watt, Phillips and Johnson<sup>1</sup>. The  $d$  spacing calculated from the (002) arcs was found to be 3.39 Å. This compares with 3.35 Å for natural graphite; it must be added that, as yet, no three-dimensional reflexions have been observed.

Transmission electron micrographs of ultramicrotomed sections<sup>4</sup>, replicas and cut ends of the fibres indicate that parts of the fibre are composed of fibrils running parallel to the fibre axis. Dark field micrographs<sup>5</sup> obtained using the (002) reflexions of the diffraction pattern confirm the X-ray estimate of crystallite size and show that the crystallites form chains along the fibre axis.

Fig. 1. An X-ray diffraction pattern from a bundle of high strength, high modulus carbon fibres; arrow indicates the fibre axis.

Fig. 2A. An electron micrograph of a cut end of a high strength, high modulus carbon fibre; arrow indicates the fibre axis. Scale length 1000 Å.

Fig. 2B. Same area as in Fig. 2A rotated about fibre axis by  $10^\circ$ .

Fig. 2 shows a cut end of a fibre in two orientations (separate and grouped fibrils with diameters in the range 250–1000 Å can be seen). As the fibre is rotated about its axis it is possible to see different groups of crystallites in the same fibril come into a position to reflect. Fibrils of similar diameter can also be seen in a two stage carbon-platinum replica (Fig. 3) of a fibre that has been embedded in a resin and longitudinally sectioned with a diamond wheel. A dark field micrograph of a longitudinal thin section is shown in Fig. 4. The areas contributing to one of the (002) arcs in the diffraction pattern are shown in light contrast. Crystallites of about 50 Å can be seen throughout the section and at the edges they are aligned in chains parallel to the fibre axis. Some of these chains are over a micron in length. Fig. 5 is an electron micrograph of a transverse ultramicrotomed section showing the distribution of diffracting crystallites—in bright field they appear in dark contrast.

It has been reported<sup>6</sup> that some elements of the morphology of rayon fibres are retained on carbonization and graphitization, and Bacon and Tang<sup>7</sup> have suggested that when cellulose is carbonized a "replica" of the original fibre structure is preserved. The same appears to be true with the raw textile fibres that we use in the production of high strength, high modulus carbon fibres, as fibrils have been reported in similar raw textile fibres<sup>8</sup> and we have also observed that the coarsely fluted outer surface

of the raw fibre is retained throughout the manufacturing process. The influence of the morphology of the raw textile fibres on the physical properties of the carbonized fibres is now being investigated.

### Voids in Solidified Iron Alloy Drops

THE surface tension of liquid metals can be readily measured by the drop-weight method, but Kelly has reported an unexpectedly wide scatter of values when he used this method<sup>1</sup>. He attributed the variation to the presence of internal voids in the drops which would alter either the contour of the drop, thus affecting measurements based on this parameter, or the presumed density of the drop used to evaluate its volume. Kelly believed that such voids could maintain themselves for an appreciable time in molten drops, and later accepted the cause to be gas present in his material. With electron bombardment devices as used by Kelly, the electron beam may impart angular momentum to the drop as a result of its being incorrectly aligned with respect to the drop surface. Thus the drops can spin about the interface between the metal drop and the rod, creating forces which, combined with the presence of dissolved gas, could lead to a stabilized void. Measurement of the rotation speed of a uniform liquid drop is virtually impossible, and thus comparison of the forces developed with the fracture stress of liquid iron has not been carried out, although Kelly confirmed in a personal communication that rotation was observed and was certainly present in the inductively heated drops in the present work to be described.

A similar observation of void formation in liquid metal drops was made by us in the course of an investigation into the oxidation of iron alloys where, in the main investigation, molten drops were allowed to fall through atmospheres containing various partial pressures of oxygen<sup>2,3</sup>. The presence of voids was investigated separately using 1.6 mm diameter iron wire of the following analysis

Element	C	S	P	N	H
Per cent	0.047%	0.03%	0.001%	0.003%	0.004 c.c./100 g

The wire was cleaned with emery paper and pickled in dilute hydrochloric acid (containing thiourea as an inhibitor) to remove any scale. Final electropolishing using a solution consisting of 60 per cent orthophosphoric acid and 40 per cent sulphuric acid with a stainless steel cathode provided a smooth polished surface.

The wire was then placed in a glass tube connected to a vacuum pump and a purified argon supply. The position of the wire could be altered through O-ring seals without breaking the vacuum or disturbing a gaseous atmosphere. The tip of the wire was then inductively melted under controlled conditions of power input and gaseous environment to form a drop the size of which was a function of the wire diameter and the liquid metal surface tension. The drop was then allowed to solidify and was sectioned for

Fig. 1. Iron drop with void ( $\times 6,8$ ).

metallographic examination by spark machining to avoid mechanical deformation and any distortion of the interface between the metal and void.

During solidification the appearance of the surface of the drop altered, a "blick" or sudden brightening occurring, indicating the solidification of an undercooled liquid<sup>4,5</sup>. This was accompanied on occasions by rupture of the skin, which left a slit in the metal surface or an erupted "bubble" at a point which might itself burst to leave a hole at the surface. In section, the drops showed large smooth sided voids connected to the outer surface through a slit (Fig. 1). Although the amount of gas present would not have given rise to such porosity in normal solidification in the absence of oxygen, the presence of dissolved gases accompanying forces produced by drop rotation seemed to be a possible source of the voids and overall shrinkage against the gas void after solidification as the cause of surface rupture. A technique was therefore devised whereby both residual carbon and any gaseous elements, for example, hydrogen and nitrogen, could be further eliminated from the iron.

The iron was annealed in a stream of wet hydrogen for 24 h at 710° C to remove carbon and nitrogen and then cooled to room temperature in dry hydrogen. The pressure used in the subsequent vacuum annealing process for hydrogen removal had to be sufficiently low to prevent oxidation at the temperatures involved; 10<sup>-5</sup> mm of mercury at 650° C for 24 h was used. Typical analyses were

	C	S	P	N	H
Hydrogen treated	0.02%	0.03%	0.001%	0.001%	0.16 c.c./100 g
Vacuum treated	0.02	0.041	0.001	0.001	Nil

Compared with the starting material, the carbon activity was reduced by less than half, and the nitrogen reduced to a third; the amount of carbon monoxide which could be formed on the drop from traces of oxygen present in the argon atmosphere was thereby substantially reduced. Hydrogen, which might come out of solution at a low pressure void, was eliminated. Subsequent melting experiments on iron purified in this way produced only very small pin-hole cavities; these were probably due to minute amounts of residual gas or to internal solidification shrinkage, although the latter is unlikely to occur in small drops of this size (2–3 mm) unless nucleated by gas<sup>6</sup>, the overall change in specific volume being achieved by plastic deformation.

This investigation indicates the necessity of eliminating, as far as possible, any gas from metal to be used in droplet studies, for example, for surface tension determination,

particularly where the heating method causes high speed rotation. Kelly (1962, personal communication) confirmed the necessity for such a step while Cline and Ferriss<sup>7</sup> came to a similar conclusion in a study of tungsten and its alloys. Certain elements had to be removed by annealing *in vacuo* at 1,850° C for 3 h to prevent the formation of voids.

## CHEMISTRY

### Reaction of Hydrogen with Graphite

In a recent communication<sup>1</sup> Gulbransen showed that reactions between graphite and hydrogen which are thermodynamically unfavourable can proceed to a measurable extent under conditions where the reaction products are rapidly removed or the system quenched. In view of this it is considered of interest to report certain observations made in these laboratories during experiments in which graphite was mechanically ground in the presence of hydrogen, and also of nitrogen. It was found that both these gases are taken up by graphite if present in the grinding chamber during the comminution process. The grinding was carried out using a vibratory ball mill fitted with gas-tight grinding chambers to which the gas was metered during grinding to maintain the pressure constant at 1 atm. The graphite was synthetic and contained less than 0.02 per cent of ash by weight, while the gases were of commercial quality at 99.9 per cent purity. The grinding medium was 0.25 in. steel balls. We concluded that the absorption of the gases must be due to some form of chemical reaction with the graphite for the following reasons. First, direct adsorption of the gases by the fresh graphite surface produced cannot wholly account for the uptake, because the extent of uptake is greater than when the graphite is first ground *in vacuo* and then placed in contact with the gas, even though the amount of fresh surface produced is greater in the latter case. Second, it is reasoned that neither hydrogen nor nitrogen reacts with the active (free radical) sites produced by fracture of the graphite planes, because we have shown that these are most readily neutralized by subsequent treatment with oxygen and that the amount of oxygen absorbed depends only on the fresh surface produced, irrespective of whether the graphite is initially ground in hydrogen, nitrogen or *in vacuo*. Finally, we have observed that graphite ground in the presence of nitrogen has a strong smell resembling that of hydrogen cyanide, whereas no such smell is detectable if the grinding is carried out *in vacuo*.

Following Gulbransen, we suggest that the reason these reactions proceed at measurable rates is the continuous subjection of the reactants to instantaneous high temperatures. These high temperatures will be generated in the frictional contacts between the steel balls used in the grinding process, and are known to be capable of reaching as high as 1,500° C (ref. 2). Because of the rapid dissipation of heat from the contacts, however, this high temperature is extremely localized, the temperature of the media

surrounding the contacts being actually less than 100° C. Thus the conditions indicated by Gulbransen for the accumulation of reaction products would appear to be fulfilled in this system.

It is proposed to publish fuller details of this work at a later date.

### Geometry of Meisenheimer Salts

IN 1942 Wheland<sup>1</sup> proposed a model for the activated complex in the aromatic electrophilic, radical and nucleophilic substitution reactions. This model was the object of semi-empirical quantum mechanical calculations and was formulated as follows

where the asterisk stays for a plus charge, an unpaired electron or a minus charge, respectively.

Since then, the model has frequently been used as a basis for theoretical investigations on the mechanism of these reactions, in the frame of localization theory<sup>2-6</sup>. It has been pointed out, however, that this model more aptly describes a possible intermediate than an activated complex<sup>7-9</sup>.

In one example of nucleophilic substitution a stable intermediate has been isolated: this is the case of the complexes of alkyl picrates with alkaline alkoxides ("Meisenheimer salts")<sup>10</sup>. An investigation of the elec-

tronic and molecular structure of the complexes of ethyl picrate with potassium or caesium ethoxide by X-ray analysis was undertaken in this laboratory and crystallographic results have been published<sup>11</sup>. This communication describes the result of a preliminary determination of the structures, at a stage where the reliability index for the caesium salt is 12.1 per cent and for the potassium salt is 14.5 per cent on about half the three-dimensional results obtainable using copper *K* $\alpha$  radiation.

Because in both structures there are two non-equivalent molecules in the asymmetric unit, the geometry of this anion has, in fact, been measured in four different environments. The averages of the experimental values for bond lengths and angles in the ring are reported in Fig. 1.

The six carbon atoms lie on a plane (within 0.04 Å); the O-C(1)-O plane is about perpendicular to the ring and the O-C(1)-O angle is 99°. The C(6)-C(1)-C(2) angle is very close to the tetrahedral value and the C(1)-C(2) distance is not far from the "best" value of the  $C_{sp^2}$ - $C_{sp^2}$  bond: 1.501 Å (ref. 12). The C-O distance is 1.43 Å.

An appropriate aromatic molecule for a comparison is perhaps 2,4,6-trinitrophenetole, whose structure has recently been reported<sup>13</sup> (see Fig. 2). In this molecule, the C-O distance is 1.37 Å and the plane determined by the oxygen and the two carbon atoms of the O Et group is approximately orthogonal to the phenyl ring; consequently, the C-O bond in this molecule can be compared with the same bonds in Meisenheimer salts. The principal part of the observed shortening is presumably due to the change from  $sp^3$  to  $sp^2$  hybridization.

In Meisenheimer salts, the carbon-carbon distances in the conjugated chain show remarkable deviations from the standard value of 1.39 Å; however, this chain should not be compared with unsubstituted benzene, because of the  $sp^3$  hybridization of C(1) and the presence of three nitro groups bonded to C(2), C(4) and C(6).

For comparison, the carbon-carbon bond lengths in an unsubstituted pentadiene anion, as predicted by a Hückel molecular orbital calculation, with inclusion of the  $\omega$ -technique, are reported in Table 1, together with the same distances in the 1,3,5-trinitropentadiene anion, where standard values for the necessary parameters have been used<sup>6</sup>.

Fig. 1.

Fig. 2.

Table 1. CARBON-CARBON DISTANCES (IN Å)

	Pentadiene anion	Trinitropentadiene anion
C(1)-C(2)	1.376	1.374
C(2)-C(3)	1.414	1.420

In general, it can be said that the experimental results completely confirm Wheland's description of the model, at least for the case of an intermediate in a nucleophilic substitution reaction.

## MOLECULAR STRUCTURE

### Transition in Cellulose in the Vicinity of $-30^{\circ}\text{C}$

THERE has been increasing interest in the investigation of thermal transitions in cellulose. It has been established that the glass transition temperature is in the region  $200^{\circ}\text{--}250^{\circ}\text{C}$ , and there is ample experimental evidence to indicate a transition at  $20^{\circ}\text{--}25^{\circ}\text{C}$ . This transition is also seen in glucose and cellobiose<sup>1-3</sup>. The purpose of this communication is to report a recently discovered transition at around  $-30^{\circ}\text{C}$ , observed in measurements of damping and thermal expansion of paper produced from wood cellulose.

Our measurements were made with an inverted torsion pendulum described elsewhere<sup>4</sup>. The paper sample (a strip,  $14.0 \times 1.5$  cm) was surrounded by a hollow brass cylinder of internal diameter 2.5 cm and length 18 cm, through which a thermostatic liquid (methanol) was circulated. The temperature was taken by thermocouples placed both in the thermostating liquid in the cylinder and at three points along the sample. The temperature gradient along the sample was less than  $0.1^{\circ}\text{C}$ . Readings were taken during both heating and cooling of the sample, and there was no obvious difference. The results shown below relate to measurements carried out during heating.

All experiments were performed in a vacuum of  $10^{-3}$  torr, which was applied 48 h before the start of the experiment. Before each reading of frequency and damping the temperature was usually kept constant for 20 min. The samples were cut from an isotropic sheet of paper of basic weight  $100\text{ g/m}^2$ , made in the laboratory. In the principal experiments a sheet made from bleached spruce sulphite cellulose of viscose quality was used. The pulp was mechanically treated (beaten, drainage resistance  $23^{\circ}\text{SR}$ ) to eliminate anomalies in mechanical behaviour known to occur with untreated pulp<sup>4</sup>. The  $\alpha$ -cellulose content of the pulp was 92.8 per cent, intrinsic viscosity was 584

$\text{cm}^3/\text{g}$  (DP 830), resin content was 0.24 per cent and ash content was 0.03 per cent. Other samples have also been investigated and their characteristics are given below.

The curves reproduced in Fig. 1 show the variation of the loss tangent and shear modulus with temperature in the bleached sulphite pulp. The maximum in the damping-temperature curves is well defined and the shape of its peak differs markedly from that of secondary maxima encountered in polymers. The appearance of a damping maximum is associated in the usual way with an inflexion of the modulus-temperature curve. The maximum occurs at about  $-30^{\circ}\text{C}$ , while the central part of the modulus inflexion lies somewhat lower. The points on curve A in Fig. 1 refer to a measurement where the sample was maintained at each temperature for 1 h, a time which was restricted to 20 min for the other measurements. The difference in the shape of the maximum may be the result of this time difference. The differences between the curves seem otherwise to be of the same order as that expected from the variation of mechanical properties between samples of paper. The increase in damping evident from curve A in Fig. 1 is caused by the maximum usually found at about  $20^{\circ}\text{--}25^{\circ}\text{C}$ . By the present method this maximum appeared at about  $35^{\circ}\text{C}$ .

For unbleached sulphate pulp with a lignin content of about 6 per cent, the maximum is no longer as pronounced as it is for a cellulose sheet of high purity. At the same time, it is shifted towards lower temperatures, as in Fig. 2. This figure also shows a  $\lg \delta$ - $T$  curve for pure cellulose II, that is, the bleached sulphite pulp of Fig. 1 which has undergone mercerization for 60 min in 18 per cent sodium hydroxide at  $20^{\circ}\text{C}$ . The transformation into cellulose II was checked by X-ray diffractograms. The position of the maximum was not changed by the transformation of cellulose I  $\rightarrow$  II. In sharp contrast to the other samples, commercial 'Cellophane', a cellulose II film softened with 15 per cent glycerol, exhibited no such transition in the interval investigated between  $-10^{\circ}$

Fig. 1. Logarithmic decrement and square of frequency for two samples of pure  $\alpha$ -cellulose. Inverted torsion pendulum. The  $\omega^2(T)$  curves of the two samples coincided. Sample A was heated more slowly than sample B.

Fig. 2. Logarithmic decrement and square of frequency for a sulphate pulp (A) and a mercerized cellulose (B). Inverted torsion pendulum.

Fig. 3. Transmission of  $\beta$ -rays versus temperature for a sample of pure  $\alpha$ -cellulose. Radiometric dilatometry was employed.

and  $-40^\circ\text{C}$ . The decrement value increased linearly from 0.25 to 0.30 as the temperature was decreased. The simultaneous increase in the value of the modulus was also linear.

Independent experimental evidence for the transition was obtained by a dilatometric technique based on the dependence of the transmission of  $\beta$ -rays on the weight/unit area of the sample at varying temperatures<sup>5</sup>. Because of the discontinuity of the thermal expansion coefficient in the vicinity of a transition, the transmission-temperature curves have a shape equivalent to that of curves obtained dilatometrically. The line reproduced in Fig. 3 and obtained with an improved radiometric technique shows a discontinuity slightly below  $-30^\circ\text{C}$  (unpublished work of Klason, Kubát and de Ruvo). From the slope of the two rectilinear portions of this curve, the coefficients of thermal expansion for the regions above and below the transition point were calculated to  $6.0 \times 10^{-5}$  and  $4.5 \times 10^{-5}$ , respectively. The sample was prepared from bleached sulphite cellulose.

The physical background of the transition presented here is not known. Its disappearance in regenerated cellulose containing glycerol indicates that it is associated with the amorphous part of cellulose. Further work is in progress, with a view to investigating the molecular nature of this transition.

## BIOPHYSICS

### Oriented Water in the Sciatic Nerve of Rabbit

A PRELIMINARY study has been made of the water found in the sciatic nerve of rabbit, which is one of the larger myelinated nerves, by proton magnetic resonance. Specimens from recently killed animals were stored in a refrigerator at about  $2^\circ\text{C}$  for periods of at least 1 h before use. In this process a certain amount of water was lost, as shown by condensation on the walls of

the containers. Approximately cylindrical samples of the nerve, about 4 mm long and 1 mm in diameter, were examined in a Varian 'A60A' spectrometer, the nerve axis being coincident with the cylindrical axis. The angle between the nerve axis and the applied magnetic field could be varied at will.

The spectra obtained are shown in Fig. 1. An appreciable amount of structure is observed and this structure depends on the orientation of the nerve within the applied field. It is consistent with the assumption that it is caused by dipolar interactions between the protons in individual water molecules. This interaction has the value  $-3\mu^2/2r^3(3\cos^2\theta - 1)$ , where  $\mu$  is the magnetic moment of the proton,  $r$  the interproton distance and  $\theta$  the angle between the proton-proton vector and the applied field direction. In normal isotropic water it is averaged to zero by molecular tumbling. This experiment suggests therefore that the bulk of the water inside the nerve is in a partially oriented state.

Fig. 1. The spectra of water in the sciatic nerve: (top) with nerve axis parallel to the applied field; (centre) the perpendicular orientation; (bottom) with the nerve axis at approximately  $54^\circ$  to the applied field direction.

The principal feature of the spectrum is a doublet the maximum splitting of which is observed when the nerve axis is parallel to the applied field. The splitting has half its maximum value in the perpendicular orientation and may be caused to be zero by setting the nerve axis at an angle of  $54^\circ 44'$  with the applied field. The orientation parameter  $S_{22}$  (ref. 1) has a value of about 0.004. The movement of the centre of the doublet as the orientation of the nerve is varied is too large to be caused by a chemical shift anisotropy and must originate in the anisotropy of the magnetic susceptibility of the nerve.

The other peaks in the spectra each show orientation dependent shifts much larger than this susceptibility shift. This suggests that these also originate in partially oriented water in a different environment and in a differently oriented state from the principal component.

It is interesting to postulate possible origins of these orientation effects. There are at least four possibilities. The water may simply be constrained by Van der Waals' forces to move in annuli which must have near molecular dimensions (about 10 Å). The orientation may be secondary orientation produced on the surface of protein molecules which are themselves aligned by the pores in the nerve. Orientation may be caused by electrostatic interactions near the fibre surface. A simple calculation suggests that the field strengths feasible are insufficient to explain the orientation observed. The water could be in a chain structure as postulated for the collagen system<sup>2</sup>. There appears to be no justification for this explanation, and the degree of orientation observed can be explained completely in terms of normal water.

In view of the normally accepted pore sizes in nerves, which are much too large to cause orientation, it is surprising that most of the water is not in its normal state.

Further work is in progress to assess the implications of these results on the structure of myelinated nerves.

## IMMUNOLOGY

### Serological Expression of Antibody Specificity for a Single Determinant of an Antigenically Complex Molecule

THE immune response to an antigenically complex molecule results in the formation of antibodies specific for one or more antigenic determinants<sup>1</sup>. In all but a few instances<sup>2</sup>, antibodies specific for individual determinants cannot be identified, which precludes the evaluation of an immune response at this level of serological specificity. It is therefore usually assumed that antibodies specific for multiple determinants are regularly produced and participate in the serological reactivity of an antiserum. Such an assumption could obscure the possibility that a given antiserum consists of antibodies specific for a single determinant. The inability of such antisera to produce precipitation<sup>3</sup> may, in turn, lead to their being considered devoid of antibody activity or their serological properties being misinterpreted. Because of these practical considerations, we decided to describe our experience of this subject.

We became aware of antibody specificity for a single antigenic determinant during a serological examination of human tetanus antitoxin, when human sera of known toxin neutralizing activities were examined by both passive agglutination and immunoelectrophoresis. The initial examination was made by passive quantitative agglutination, a procedure previously used to compare antibody combining properties<sup>4</sup>. In its present application, tetanus toxoid was coupled to human group O red cells<sup>5</sup>. As we anticipated, there was no correlation between the magnitude of the quantitative agglutination curve and neutralizing activity (Fig. 1). Nevertheless, it was interesting that one antiserum with less than 1 U of neutralizing activity/ml. gave a strong agglutination curve. Additional examples were found among other available low-neutralizing sera (Fig. 2).

Fig. 1. Quantitative agglutination curves of human sera of different tetanus toxin neutralizing activities.

Fig. 2. Agglutinin activity of selected antisera in which little or no neutralizing activity was demonstrable.

Selected examples of both high- and low-neutralizing sera were compared by immunoelectrophoresis. All the low-neutralizing sera, and one of the high-neutralizing sera, failed to give a precipitin band. This was particularly surprising because some of the non-precipitating sera had given stronger agglutination curves than several of the precipitating sera. The failure of precipitation among the strongly agglutinating sera could not be reasonably ascribed to either low antibody concentration or affinity, and so we looked for an alternative explanation.

In comparing the mechanics of precipitation and passive agglutination, it became apparent that, although both reactions require lattice formation, antisera specific for a single antigenic determinant would behave quite differently; an antiserum specific for a non-repeating antigenic determinant would be incapable of lattice formation. It was, however, evident that if such an antiserum reacted with particles to which many antigen molecules were coupled, as in passive agglutination, then ample opportunity for lattice formation would exist. This principle, regularly considered in the assay of antibodies specific for simple chemical haptens<sup>6</sup>, seemed directly applicable to other observations. We concluded that the strongly agglutinating, non-precipitating antisera encountered in this investigation were made up largely of antibodies specific for a single, non-repeating, antigenic determinant. Evidence supporting this conclusion was obtained later.

Two related experiments were carried out in which advantage was taken of previously demonstrated properties of individual antisera. The first experiment consisted of mixing the one available example of a non-precipitating, high-neutralizing serum (>20 U/ml.) in varying proportions with a non-precipitating, low-neutralizing serum (<1 U/ml.) and testing with tetanus toxoid by immunodiffusion. Neither of these sera alone produced detectable precipitation of the tetanus toxoid. When combined in equal proportions, a comparatively strong precipitin band was formed, indicating that the two sera must have been specific for two different determinants, and that both determinants were present on the same molecule. In other circumstances, the non-precipitating character of such an antiserum would undoubtedly have been misinterpreted. In the second experiment a papain digest<sup>7</sup> of the  $\gamma$ -G antibody from a strongly agglutinating, non-precipitating, low-neutralizing (<1 U/ml.) serum was mixed with different precipitating, high-neutralizing sera in the hope of observing inhibition of precipitation with

tetanus toxoid. Inhibition of precipitation was observed in one of the first three high-neutralizing sera tested by immunodiffusion. An undigested sample of the same  $\gamma$ -G fraction did not alter precipitation. This precipitating, high-neutralizing serum was probably specific for no more than two determinants and inhibition was probably caused by the blocking of one of these determinants by the univalent antibody digest.

These experimental findings appear to agree with our previous conclusion. We therefore suggest that the combined use of precipitation and passive agglutination could be useful in the recognition of antisera specific for a single antigenic determinant.

This work was supported by a general research support grant, Michael Reese Hospital and Medical Center. We thank H. B. Devlin of Parke, Davis and Co. for human tetanus antitoxin sera of known neutralizing potencies determined by a mouse assay procedure.

## Immunoglobulins in Tibetans

INFORMATION about increased gamma-globulins in certain ethnic communities is rare and as far as we know extends only to Navajo Indians, Puerto Ricans and certain American Negroes<sup>1-3</sup>. There has been no convincing explanation for this phenomenon. We discuss here racial differences in the synthesis of gamma-globulins, and increased exposure to chronic infections, the latter resulting in an increased production of humoral antibodies. Chronic liver disease can easily be excluded as a cause.

We have found low serum lipids as well as generally increased gamma-globulins in Tibetans in Nepal and Switzerland<sup>4</sup>. Now we have examined several serum components of a group of Tibetan refugees resettled in Switzerland by the Swiss Red Cross.

This communication presents the results of an examination of the immunological components of the serum proteins in seventy Tibetan males and females aged between 30 and 50. The results are compared with those of twenty-one matched Swiss controls of a similar age and without known illness.

Total proteins were determined in fasting serum samples; paper electrophoresis was performed, and immunoglobulins were separated on a semi-quantitative basis by double diffusion in agar-gel (differentiation of gamma-A and gamma-M).

Table 1

	Tibetans	Swiss	P-value
Serum samples (N)	41	22	—
Age ( $\bar{x}$ )	38.5	34.5	—
Total proteins (g per cent)	7.07 $\pm$ 0.46	6.86 $\pm$ 0.33	0.05
Gamma-globulins (g per cent)	1.58 $\pm$ 0.25	1.20 $\pm$ 0.14	0.001
Gamma-A-globulins (mean titre)	1 : 236	1 : 195	0.05
Gamma-M-globulins (mean titre)	1 : 37	1 : 31	0.05

Table 1 shows the results as mean values with the standard deviation. A further analysis was made according to age and sex, but this analysis did not yield any further information.

The total gamma-globulins in Tibetans are greater than in the Swiss controls, the difference being statistically significant ( $P < 0.001$ ). The mean value for the immunoglobulins gamma-A and gamma-M is also greater in the Tibetans but is less pronounced and these differences do not attain statistical significance. The more marked increase of the total gamma-globulins in comparison with the gamma-A and gamma-M values might be largely the result of a higher gamma-G subfraction.

We have no explanation for these findings. A substantial rate of manifest infection or liver disease in the Tibetans can be excluded. Racial and environmental factors require consideration, and further elucidation may be obtained by observation and re-examination of Tibetans abroad.

## Post-embedding Staining with Ferritin Labelled Antibodies

THE ferritin labelled antibody technique<sup>1</sup> has been widely used for the location of antigens at the cellular and sub-cellular level<sup>2</sup>. There are two possible methods of applying the technique: (a) pre-embedding staining in which antigen is allowed to react with the labelled antibody before the cells are processed and sectioned in preparation for electron microscopy; and (b) post-embedding staining in which labelled antibody is applied to and reacts with the antigen in suitably fixed and embedded thin sections. Almost all published investigations have been carried out using the pre-embedding staining technique. Surface antigens are readily located by this method, but intracellular antigens can only be located after treatments such as freezing and thawing and disintegration which enable the labelled antibody to penetrate within the cell. The technical difficulties associated with the post-embedding staining technique are complicated by the non-specific attraction for ferritin of all commonly used embedding media, including butyl methacrylate-ethyl methacrylate co-polymer, polyglycol methacrylate, vestopal and epon<sup>3</sup>. The phenomenon was attributed by these workers to the non-ionic character of the embedding media, and they attempted to develop a new embedding medium with ionic charges which allowed wetting, thus reducing non-specific adsorption. Preliminary results with viral antigens in the polyampholyte embedding medium which they developed were very encouraging.

The present communication deals with our experience using this embedding medium in the location of bacterial antigens.

The strain used throughout this work was *Bacillus cereus*, variety terminalis. Antisera were prepared against both spores and vegetative cells<sup>4</sup> and coupled to ferritin using toluene 2 : 4 di-isocyanate<sup>5</sup>. A young vegetative cell suspension was prepared by thoroughly washing the deposit from a 12 h broth culture fixed overnight in 10 per cent buffered formalin, pH 7.2, or in 2.5 per cent buffered glutaraldehyde pH 7.2-7.4 for 2 h. After thorough washing in saline the organisms were embedded in the polyampholyte medium using the methods described by Singer and McLean<sup>3</sup>. Polymerization was initiated by heating at 60° C overnight and completed by a further period of curing for 3 days at room temperature. Sections

were cut on an L.K.B. 'Ultratome', using a cutting speed of 50 mm/sec, and collected on 400 mesh grids without supporting membrane. The grids were then stained with ferritin labelled antibody to the vegetative cell or ferritin labelled antibody to the spore by either of two methods. In the first method the grids were floated on to a drop of the labelled antibody and left for half an hour. After this the grids were lifted with forceps and rinsed by gentle agitation in a beaker of saline. In the second method, for which we are indebted to Dr S. J. Singer, the grids were held in forceps and immersed in a small receptacle containing approximately 1-2 ml. of phosphate buffered saline, pH 7.2, for 5-10 min. One drop of the appropriate ferritin labelled antibody was then added to the buffered saline, thoroughly mixed and left for a period of half an

Fig. 1. Electron micrograph of section of *B. cereus* in the polyampholyte embedding medium stained with method 1, fixed in 10 per cent buffered formalin.

Fig. 2. Electron micrograph of section of *B. cereus* in the polyampholyte embedding medium stained with method 2, fixed in 10 per cent buffered formalin.

hour with occasional agitation. Phosphate buffered saline, pH 7.2, was then used to flush out the uncombined labelled antibody, after which the grid was washed for a further 10 min. At no time during the staining process was the grid allowed to dry. After a quick rinse in distilled water the grids were examined in a Philips 'EM 200' electron microscope at 60 kV.

Using method (1) ferritin particles were seen adhering to the embedding medium throughout the sections (Fig. 1), making specific staining difficult to differentiate. Using method (2) intense staining with antibody labelled with ferritin of the vegetative cell was observed only along the cell wall of the organisms, and background staining was minimal (Fig. 2). Contrast was very poor after formalin fixation, but rather better after glutaraldehyde fixation. No specific or non-specific staining of the vegetative cell was observed after treatment with ferritin labelled antibody to the spore.

The initial results obtained with the polyampholyte using method (1) were very disappointing and were no better than those obtained using normal butyl methacrylate-ethyl methacrylate co-polymer. Using method (2), however, background staining was reduced to a minimum and much better results were obtained. This method is designed to prevent surface-denatured antibody from coming into contact with the section (S. J. Singer, personal communication). Our results support those of Singer and McLean<sup>3</sup> and indicate that their approach to the problems of post-embedding staining in the development of an ionic embedding medium was valid. Unfortunately the method has not yet been developed to a routine stage. Some variation in results has been noted with different batches of component materials and with the age of the block; in general, the background staining decreases with increasing block age.

It would appear that antigenic sites survive embedding in the polyampholyte embedding medium and are available for combining with the labelled antibody. In view of the usefulness of the post-embedding staining techniques in solving problems of the location of intracellular antigens it is hoped that these preliminary results will provide the stimulus for further development of the method.

### Antigen Stimulated DNA and RNA Synthesis in Spleen Cell Suspensions from Immunized Rabbits

SEVERAL metabolic inhibitors have been shown to inhibit the initiation of antibody synthesis in a variety of *in vitro* systems (see Table 1), and it has been suggested that certain of these agents may inhibit antibody formation by suppressing the formation of the messenger RNA which directs the synthesis of the antibody molecule, although other explanations have been considered<sup>3,4</sup>. In

Table 1. INHIBITION OF THE INITIATION OF ANTIBODY SYNTHESIS *in vitro*

References	Culture system	Inhibitor	µg/ml.
1	Spleen cell fragments	5 BUdR	6
2	Spleen cell fragments	Chloramphenicol	5-20
3	Spleen cell fragments	Chloramphenicol	20-50
	Spleen cell fragments	Actinomycin	8
4	Spleen cell fragments	Actinomycin	0.06

Fig. 1. Control and antigen stimulated cultures are represented by open and closed circles, respectively. Nucleic acid synthesis in spleen cell suspensions from previously immunized rabbits was stimulated by the addition of the specific antigen.  $1.5 \times 10^7$  spleen cells were incubated in 1.5 ml. of medium containing the inhibitor indicated. DNA and RNA synthesis were measured by the incorporation of tritiated thymidine (2  $\mu$ c. at 80 mc./mmole/culture) or cytidine (0.4  $\mu$ c. at 40 mc./mmole/culture) in the period 24–48 h after the start of incubation. The results are expressed as per cent inhibition of the incorporation seen in the absence of the inhibitor. Incorporation of thymidine or cytidine in the antigen containing cultures was, on average, approximately twice that observed in the control cultures.

these studies the effect of the inhibitor was assessed after several days' incubation with the cells. Subsequent studies in which much shorter time periods were used have suggested that this may be the case<sup>5,6</sup>. It has been shown, however, that the antibody forming cell population arises by a rapid proliferation of a much smaller number of precursor cells, both *in vivo*<sup>7-9</sup> and *in vitro*<sup>10-12</sup>, in both the primary and secondary response. It is clear that any agent which inhibits such proliferation will reduce the subsequent synthesis of antibody in experiments extended over longer periods of time. It is also probable that specific inhibitors of RNA and protein synthesis will subsequently affect DNA synthesis, providing the time of incubation with the drug is sufficiently prolonged. It was therefore of some interest to measure the concentration of a selected group of metabolic antagonists which would inhibit DNA, RNA and protein

synthesis in an appropriate *in vitro* system. The results of such a study are recorded in Fig. 1.

Spleen cell suspensions from normal or previously immunized rabbits were incubated<sup>13</sup> in a modified Eagle's medium in the presence or absence of the metabolic antagonists, as indicated. The rate of DNA synthesis was determined by the uptake of tritiated thymidine in the period of 24–48 h after the start of incubation, and the inhibitor was present for the whole incubation period. The rate of RNA synthesis was similarly determined using tritiated cytidine. In this system the addition of very low concentrations of metabolic antagonist, except chloramphenicol, can markedly inhibit DNA and RNA synthesis. The concentration of drug required to effect an inhibition is comparable with previously reported values when cultures of other mammalian cells were treated with actinomycin D<sup>15-17</sup>, puromycin<sup>17,18</sup>, mitomycin<sup>17,19</sup> and chloramphenicol<sup>17</sup>. Similar inhibitory effects were seen in antigen stimulated and control cultures. Inhibition of DNA synthesis is known to depress the initiation of antibody formation<sup>1</sup>. It is therefore probable that the inhibition of the initiation of antibody synthesis seen in other studies<sup>3,4</sup> was a secondary consequence of the suppression of cell division.

### Immunological Reactivity of Peptides related to Angiotensin

THE production of antibodies to angiotensin II has made measurement of this peptide by radioimmunoassay possible<sup>1</sup>. While this procedure is extremely sensitive, the specificity of the method is determined by the degree to which related forms of the molecule will react with the same antiserum and thus register as angiotensin II in the assay. Because the measurement of angiotensin II in body fluids is of cardinal importance in the elucidation of the role of the renin-angiotensin system in physiological processes such as vascular reactivity and aldosterone biosynthesis, it is essential to determine whether the biologically active octapeptide is specifically estimated by the results obtained from radioimmunoassay.

This problem was examined in a radioimmunoassay system for angiotensin II which uses antibodies to val 5

Fig. 1. The displacement of  $^{125}\text{I}$ -angiotensin II amide from combination with its antiserum by angiotensin II amide (●—●), the hexapeptide des-asp, arg, angiotensin II (○—○), angiotensin I (■—■), and the tetradecapeptide renin substrate (□—□). "Free counts",  $^{125}\text{I}$ -angiotensin II amide displaced from antiserum to the ion exchange resin 'CG-400' (OH<sup>-</sup>) by unlabelled peptide. U, Upper limit of assay (no antiserum present). L, Lower limit of assay (no peptide present).

angiotensin II amide, and ion exchange to achieve separation of bound and free tracer angiotensin II<sup>2</sup>. The antibodies were generated by immunization of rabbits with a conjugate consisting of angiotensin II amide coupled to porcine gamma-globulin, and were detected by their ability to bind radioiodinated angiotensin II amide. In the assay, the presence of unlabelled angiotensin II results in displacement of  $^{125}\text{I}$ -angiotensin from the antibody bound form to the "free" form, which is then adsorbed to the anion exchange resin 'CG-400' (OH<sup>-</sup>) and counted. The radioactivity of the ion exchange resin (or "free" tracer) thus rises toward a maximum with the addition of increasing quantities of angiotensin II or related peptides capable of reacting with the antiserum. The  $\alpha$  and  $\beta$  aspartyl forms of angiotensin II were found to be equally reactive as the amide, indicating that configurational changes around the N-terminus of the molecule do not affect immunological reactivity and that the naturally occurring form of the peptide was detected by these antibodies. On the other hand, the decapeptide angiotensin I showed very little cross reaction in the assay, possessing only 2.5 per cent of the immunological potency of angiotensin II. Of the other peptides which occur in blood, bradykinin, vasopressin and adrenocorticotrophic hormone were tested and found to be completely unreactive.

Because the biological inactivation of angiotensin II proceeds in part by the removal of amino-acid residues from the N-terminal end of the molecule<sup>3</sup>, it is essential

to determine the reactivity of fragments of the molecule which may occur *in vivo* during this process of degradation. The hexapeptide formed by the removal of the two N-terminal amino-acid residues from angiotensin II has been shown to be biologically inert<sup>4</sup>. The effect of this peptide on the radioimmunoassay system for angiotensin II is shown in Fig. 1. It is apparent that considerable cross reaction occurs, the hexapeptide being of the same order of immunological potency as angiotensin II amide at low concentrations, though of decreased potency at higher concentrations. To extend the previous finding on the reactivity of angiotensin I, the effects of this peptide and the tetradecapeptide renin substrate were also examined. The earlier observation on the low reactivity of angiotensin I was confirmed, and the immunological potency of the tetradecapeptide shown to be of an even lower order. From the results of five experiments similar to that shown in Fig. 1, the following conclusions were reached. Angiotensin I exhibited only 2.4 per cent of the immunological potency of angiotensin II. The tetradecapeptide showed only 35 per cent of the immunological potency of angiotensin I. These two peptides did not usually begin to register in the assay until at least 8 ng was present. 0.5 ng of angiotensin II was well detected by the assay, occupying approximately 50 per cent of the total range. The hexapeptide was more reactive than angiotensin II when less than 2 ng was present, and less reactive when greater quantities were present. This information is illustrated in Fig. 2.

It is apparent that the "antigenic site" of angiotensin is more affected by additions to the C-terminal end of the molecule than by alteration of the N-terminus. Goodfriend *et al.* used inhibition of complement fixation to show that the immunological reactivity of angiotensin was little affected by modifications at position 1 (ref. 5) but in contrast to the present results detected only quite low reactivity (3 per cent) in the 1, 2 des val 5 angiotensin analogue which we found to react quite strongly with antibodies to angiotensin. Apart from the possibility of differing specificities of the two antisera used for these studies, it is possible that the different nature of the two assays could contribute to this difference in apparent reactivity of the hexapeptide. It should also be emphasized that although low concentrations of the hexapeptide react quite strongly with anti-angiotensin in the radioimmunoassay, there is a considerable fall in potency relative to angiotensin II at higher concentrations in this assay.

Because of the low immunological potency of angiotensin I and the tetradecapeptide renin substrate, these peptides are unlikely to interfere with the measurement of angiotensin II extracted from body fluids and incubation media. The strong reactivity of the hexapeptide at low concentrations, however, could possibly comprise the measurement of angiotensin II by this radioimmunoassay. To avoid invalidation of the assay results by the presence of this peptide, it may be necessary to include a chromato-

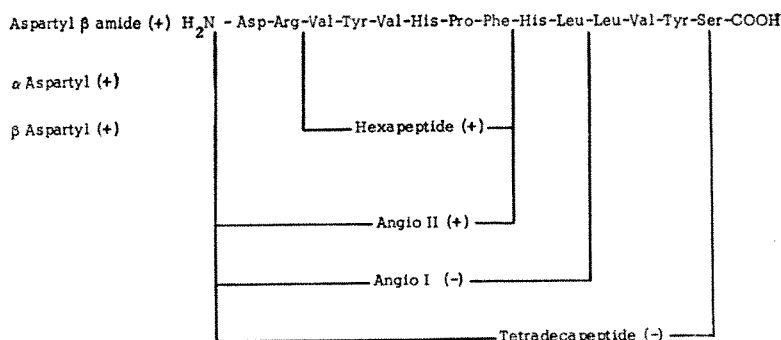

Fig. 2. Diagram of the immunological reactivity of the angiotensin series of peptides (+), Strongly reactive; (-), weakly reactive.

graphic or electrophoretic step to separate the hexapeptide from angiotensin II in blood extracts before the immunoassay is performed. Depending on the rate of degradation of the hexapeptide relative to that of its formation from angiotensin II, the measurement of the level of this fragment following such a fractionation step could provide a useful reflexion of angiotensin II metabolism *in vivo* and *in vitro*.

We thank Dr B. Riniker and Dr F. Gross of Ciba, Basle, for angiotensin, 1,2 des-angiotensin and tetradecapeptide. This work was partly supported by a grant from the National Heart Foundation of Australia.

*Note added in proof.* Dietrich<sup>6</sup> has recently reported that the C-terminal of angiotensin II is of the utmost importance for immunological specificity, whereas the N-terminal is relatively unimportant in this regard, and has suggested that antibody and biological receptors for angiotensin II may not require the same structural features.

## Relationship between the Subunits and "T" Antigens of Adenovirus Type 12

In previous reports, we have described the separation of the group-specific ("A" antigen) and type-specific ("C" antigen) subunits of adenovirus 12 (ref. 1) and the "T" antigens<sup>2</sup> of the highly oncogenic group A adenoviruses, and we have described, using indirect methods, the production of type-specific antigen in virus free hamster tumour cells induced by adenovirus type 12 (ref. 3).

This communication describes the separation of the tumour cell antigens induced by adenovirus 12, in order to compare these components with those found in the

infected cells, because such components might differ in form, content or amount if present in the tumour cell. The tumour antigens were prepared in the following manner. A primary hamster tumour induced by adenovirus 12 of a size greater than 50 mm was excised, and debrided of all necrotic tissue. The tissue was suspended in Eagle basal media with penicillin and streptomycin at 4° C, and the tissue was broken up mechanically with a syringe and successively smaller needles, with repeated washing. When fine enough to be drawn into a 17 gauge needle, 1 c.c. was inoculated into each animal above the right flank. When the tumour was larger than 40 mm, the animal was bled and killed. The tumour was removed and debrided of all necrotic tissue. It was then minced, washed and spun at 1,500 r.p.m. for 19 min at 4° C three or four times. The tumour was weighed and a 16.7 per cent w/v suspension in Eagle basal media was prepared. This suspension was homogenized with a 'Virtis' homogenizer at low speed for 15 min and at medium speed for 15 sec at 4° C. The bulk of the material was frozen at -60° C and a portion of each tumour was frozen separately and tested for complement-fixing (CF) reactivity with hamster tumour antisera. Those tumours with a CF titre of more than 1:16 with carefully standardized hamster tumour sera were used in the present experiments. The method used to separate the tumour antigens was the same as that described previously for the separation of adenovirus 12 "T" antigens from the infected cell<sup>2</sup>, except that the tumour was homogenized by hand before separation: 3 ml. of homogenized antigen preparation was layered on top of a 1.3 × 61 cm 'Sephadex G-100' column under 2.9 ml. buffer and eluted (15 cm water pressure above the top of the column) with 0.01 molar phosphate buffer, pH 7.0, at a flow rate of 0.4 ml./min. Because centrifugation resulted in antigenic loss, we eliminated fast-sedimenting particles and a cell debris from unclarified starting materials by means of a preliminary partial separation on 'Sephadex' carried out as follows. The void volume of each column, about 25 ml., was collected, followed by consecutive collections of 20 ml. (Pool A), 12.5 ml. (Pool B), and 35 ml. (Pool C). Similar collections from each of eleven columns were pooled and concentrated ten times. Pool A was sonicated in a sonic oscillator (50 W, 9 kc/s) for 1 min at an output voltage of 180 V. A portion of each of the three pools was then set aside to be used as a control. Eight fresh 'Sephadex' columns, three labelled A, two labelled B, and three labelled C, were then loaded with 3.0 ml. of the respective concentrated A, B and C pools. Each was applied directly on to the top of the gel and void volume (25 ml.) plus four fractions (12.5, 5.0, 12.5 and 20.0 ml., respectively) were

Table 2. SUMMARY OF KNOWN CHARACTERISTICS OF THE HIGHLY ONCOGENIC GROUP A ADENOVIRUS 12 SUBUNITS AND T ANTIGENS

Adenovirus 12 T antigen (type-specific)	—molecular weight about 80,000. —heat unstable. —does not react with rabbit anti-group (A) or anti-type (C) specific virion antisera or with narrow-reacting hamster tumour sera. —does react with hamster tumour sera which is reactive both with adenovirus 12 T complex and with purified C antigen. —is sensitive to FUDR. —is probably the form C antigen takes in the tumour. —is inseparable of component parts on DEAE when purified T antigen is used. —is separable of component parts on DEAE when purified 80,000 tumour antigen is used. —is present in nuclear, microsomal subcellular particulates. —separated from washed, infected cells by triple-cycling on 'Sephadex G-100', followed by gel electrophoresis.
Adenovirus 12 T antigen (group-specific)	—molecular weight of approximately 20,000. —heat stable. —sensitive to ether and to several freezings and thawings. —reacts with all group A adenovirus hamster tumour sera. —is not sensitive to FUDR. —is associated with or contains a phospholipid protein. —does not react with rabbit anti-group or anti-type specific virion antisera. —is present in nuclear subcellular particulates. —separation from washed, infected cells by double-cycling on 'Sephadex G-100' and a third cycle on one of the lower-numbered 'Sephadexes', followed by gel electrophoresis.
Adenovirus 12 type-specific subunit (C antigen)	—molecular weight of approximately 63,000. —heat stable. —double-cycled on DEAE is semi-sensitive to ether, quad-cycled is not. —does not react with rabbit anti-group specific sera or with narrow-reacting hamster tumour sera. —does react with rabbit anti-type specific sera and with certain hamster tumour sera demonstrated to have C antibody. —is often associated with a component with a mol. wt. of 137,000 which has not been characterized. —separated from late harvested, infected cell supernates by five cycles on DEAE or by double cycles on DEAE followed by gel electrophoresis.
Adenovirus 12 group-specific subunit (A antigen)	—heat stable, reacts with rabbit anti-group specific sera. —not sensitive to ether, partially sensitive to trypsin. —separated in same manner as C antigen. —exists naturally as a dimer (mol. wt. 376,000) and in ratio of one dimerized A antigen to C antigen, which suggests hook-up type 1 over type 2.

collected. Concentration was carried out with 'Diaflo' model 50 ultrafiltration cells, using UM-1 'Diaflo' membranes, operated at a pressure of 30 lb./in.<sup>2</sup>.

For comparison, a typical second cycle separation and recovery of adenovirus 12 "T" antigens from crude late gathered infected KB cells<sup>2</sup> is shown in Table 1. The antigen which was recovered from the second cycle of pool B (fractions II and III) was found to have a molecular

weight of about 80,000 and the antigen recovered from column C (fraction III) was found to have a molecular weight of about 20,000 (ref. 2).

A summary of what we know so far about two compounds from infected cells which react with hamster tumour antisera and about subunits of adenovirus 12 is shown in Table 2.

The second cycle separation and recovery of adenovirus 12 hamster tumour antigens from 'Sephadex' columns are shown in Table 3. If one compares the separation of the infected cells in Table 1 with the separation of the tumour cells in Table 3, it can be seen that a component of lower molecular weight from column C pool III is present in both the infected cells and in the tumour cells. This tumour fraction is likewise sensitive to ether and to freezing and thawing and is stable at 56° C for 30 min. It can be seen that there was no CF reacting component from column B pool II. After this fraction was cycled on DEAE (ref. 1) a whole type-specific (C antigen) was present, as measured in complement-fixation tests with specific anti-C rabbit sera. Thus it might be concluded that there was present in the tumour cell a partially fragmented type-specific antigen which was in some manner covered or interrelated with the "T" antigen. The separated "T" component (column C fraction III) was measured more strongly by the narrow-reacting hamster sera (III). The partially fragmented or unstable type-specific component was not measurable in the separated fraction II of column B, but, apparently, it was reassembled or brought together or altered in some manner on recycling over DEAE and gave a complement fixing reaction with type-specific antisera.

We suggest that the type-specific antigen was somehow covered by or attached to the phospholipid-containing or -associated "T" antigen in the tumour cell. In the tissue culture system there may have been greater interaction and a more cohesive attachment due to the large number of virion components in that system. In addition, the higher molecular weight "T" component in the infected cell was collected from both early and late cells<sup>2</sup> while the type-specific antigen was separated only from cells collected late<sup>1</sup> in amounts sufficient for detection by complement-fixation. Thus it is possible that the higher molecular weight "T" component in the infected cell may be some form of precursor to the type-specific subunit. Or, in the tumour cell, the "T" coat may have been more easily removed. We were unable to break apart the higher molecular weight component derived from the infected cells by using the same methods; however, when a similar fraction was separated from the tumour cell on 'Sephadex', it was possible to extract a CF reacting

type-specific subunit by using our method of separation on DEAE (ref. 1) followed by the 'Diaflo' ultrafiltration concentration method. We are not sure whether "T" antigen is internally connected to virion antigen; indeed, this may be a matter of semantics: one would call any internal component a "virion" antigen. It is noteworthy, however, that in the 'Sephadex' experiments with infected cells<sup>2</sup> a portion of the lower molecular weight component always remained associated with group-specific antigens (pool A fraction 1) and was not released by sonication or by repeated separation on 'Sephadex'.

*In vivo*, it is possible that the type-specific "T" antigens detach from the virion capsid and remain associated in the tissue cells for indefinite periods of time. We plan to explore this hypothesis further using an electron microscope, with other sera prepared against separated whole and disintegrated antigens and virion, and by purification and chemical analyses of these, and perhaps other, separated antigens.

We thank the following for technical assistance: H. C. Turner of the Laboratory for Virus Diseases, National Institutes of Health, for complement-fixation testing (through the courtesy of Dr R. J. Huebner); T. Rothstein and S. Alexander, for care of animals and assistance with tumour excisions; and O. B. Lee for assistance with 'Sephadex' separations.

### Heat-labile Macroglobulin revealed in Adenovirus 12 Tumour Sera by Gel Electrophoresis

THERE are two important differences in the way serum proteins separate by zone electrophoresis which employs gels, when compared with paper or moving boundary electrophoresis. First, the sieving effect of the gel alters the mobilities of the proteins and, second, more fractions are resolved. Varying the pore size of the gels excludes from or permits movement of the proteins based on the molecular size and shape relative to the gel pore size.

Previously, we reported the location of complement-fixing antibodies to adenovirus 12 tumour and "T" antigens in the 7S gamma-globulin fractions of tumour bearing hamsters<sup>1</sup>. The "T" and tumour antigen complexes previously had been shown by separation studies to have at least one heat stable and one heat labile component<sup>2</sup> and some quantitative differences in reactivity of the 7S fraction with tumour and "T" antigens from different sources were noted. In addition, the location of antiviral complement-fixing antibody in gamma-globulin fractions of sera from a child at three different times before and after infection with adenovirus type 31 was found almost entirely in the 7S fraction and this was later confirmed in neutralization tests and in other test sera (unpublished results of Vargosko and Hollinshead). This second paper in our series of investigations dealing with adenovirus-related antibodies is a study of the whole serum, 19S and 7S fractions of normal and adenovirus 12-tumour bearing hamsters using polyacrylamide gel disc electrophoresis.

The sera from two normal and four tumour bearing hamsters were investigated. At the time the sera were

obtained the animals were 45–90 days old, and the tumour sizes were 35–70 mm across. Of the tumour bearing animals two were litter mates inoculated at birth with adenovirus type 12 and two were unrelated adult animals that received tumour cells from the fifth passage of an adenovirus 12-induced tumour. Inoculations were given subcutaneously and both males and females were used. Sera from the tumour bearing animals had complement-fixing titres of  $>1:64$  using LID adenovirus 12 tumour antigen pool No. 10 diluted 1:4. Sera were stored at  $-70^{\circ}\text{C}$  in samples of 1–3 ml. and no serum was more than 9 months old.

Separation of the whole serum into the 19S and 7S fractions was by the method of Kunkel<sup>3</sup> using 10 per cent to 37 per cent (w/v) sucrose. The 7S fraction was removed by puncturing the side of the tube and the 19S fraction by bottom puncture. A sample of 1 ml. of each fraction was concentrated to 0.2 ml. by the method of Kohn<sup>4</sup>. Electrophoresis of the whole serum and the 7S fraction on polyacrylamide gel was performed as described by Ornstein<sup>5</sup>. When the 19S fraction was investigated, a separating gel of 4.2 per cent was made by diluting the standard 7 per cent acrylamide gel solution with distilled water. By letting the gel stand overnight in the column at room temperature a more rigid workable material developed. The stacking and sample gel were then applied before electrophoresis. In order to obtain clear bands with the 19S fraction a modified sample gel was prepared. A saturated solution of sucrose was used instead of the standard 40 per cent stock solution generally recommended. A 3:5 ratio of sample to gel was employed. A *tris* glycine buffer, pH 9.5 and ionic strength 0.5 molar, was used and all the samples were run at a current 2.5 m.amp/tube for 1 h.

To test for the presence of the  $\text{C}_1$  macroglobulin component of complement, 0.15 molar disodium ethylene tetra-acetic acid (EDTA) was prepared and titrated to pH 7.4 with 0.1 molar sodium hydroxide. Equal parts of EDTA and serum were mixed and allowed to equilibrate for 30 min at  $4^{\circ}\text{C}$  before sucrose density separation.

When 5  $\lambda$  of undiluted whole serum was separated by electrophoresis the number and location of the bands obtained were strikingly similar for normal and tumour sera. Between nine and eleven bands were found in each, with the most prominent disks being albumin and transferrin. There were, however, quantitative differences when normal and tumour sera were compared (Fig. 1).

Twenty-five  $\lambda$  of the 7S sucrose fraction was used and again there was no difference between tumour and normal hamster sera except in the thickness of the bands. Because the 7S fraction migrated as a diffuse band in the upper gel and was obscured by other unrelated proteins, 7S

Fig. 1. Electrophoresis of normal hamster serum (left) and adenovirus type 12 tumour serum (right) using 7 per cent polyacrylamide gel. The origin (cathode) is at the top.

Fig. 2. Separation of unheated and heated serum of the 19S fractions of normal hamster (A) and hamster with an adenovirus type 12 tumour (B) using 4.2 per cent gel. There is no difference in normal heated hamster serum when compared with unheated normal serum. In the unheated tumour serum (B), however, two dark bands are present instead of one, and the upper dark band almost completely disappears on heating.

fractions were extracted with rivanol before electrophoresis and again only a quantitative difference was noted between normal and tumour sera.

Reduction of the separating gel concentrations to 4.2 per cent allowed the macroglobulins to migrate readily into the gel. A marked difference between the 19S fractions of normal and tumour sera was noted. As can be seen in Fig. 2, the four bands which appeared in the upper part of the separating gel in the normal sera differed from the four bands identified in the tumour sera. When normal serum was heated to 56°C for 30 min there was no alteration in the bands after electrophoresis compared with the unheated normal serum. When the tumour serum was heated in the same conditions, however, one band almost completely disappeared with only a trace of the protein being identified. Another disk appeared as a hazy band at the very top of the separating gel (Fig. 2), and probably represents heat-agglutinated protein. These differences between the 19S fractions could be better delineated by using a 50λ sample.

Although there was no proof that the heat labile macroglobulin of the tumour bearing hamsters contained the 19S antibody, it was possible that this represented the C<sub>1</sub> component of complement. Naff *et al.*<sup>6</sup> have shown that C<sub>1</sub> is a macroglobulin with a sediment coefficient of 19S. They have also found that this macroglobulin in the presence of EDTA is broken down into three subunits that sediment as 11S, 7S and 4S proteins. Treating our sera with 0.15 molar EDTA did not alter the 19S bands of the unheated tumour or normal sera; thus by indirect evidence, the macroglobulin bands were not part of the complement system.

In conclusion, in the hamster with a tumour induced by adenovirus 12 there is a change in the proteins in the whole serum and in the 7S fraction as determined by gel electrophoresis when compared with normal serum. At the time the complement-fixing antigens in the tumour and 7S serum antibodies were at their peak a new serum protein in the 19S fraction appeared that was not present in normal serum. This fraction was almost completely destroyed by subjecting the serum to a temperature of 56°C for 30 min and may account for the low titres of 19S antibody in the tumour sera<sup>1</sup>.

Takemoto *et al.*<sup>7</sup>, using a fluorescent antibody test, found a heat labile fraction in polyoma virus-induced tumour antiserum responsible for nuclear fluorescence. This heat labile serum component was also not entirely destroyed by heating to 56°C for 30 min, for minimal fluorescence persisted. We are investigating adenovirus 12 and SV40 virus to determine whether the heat labile serum fractions of sera of tumour bearing hamsters have

similar characteristics and whether they are located in the 19S fraction.

Of more importance, Takemoto's findings suggest to us that there may be a difference between the fluorescent and complement fixing antigens, because the latter reacts with a heat stable antibody.

We thank Dr R. J. Huebner and Mr H. C. Turner for the hamster sera and complement-fixation tests.

### Delayed Hypersensitivity *in vitro*

DURING investigations of the effects of induced immune paralysis on delayed hypersensitivity *in vivo* and *in vitro*, evidence has been found<sup>1,2</sup> for a diffusible factor which is released from the sensitive cells in contact with the antigen; this factor inhibits migration of cells from a normal lymph node explant. These investigations have been extended and the results will be summarized here.

Delayed hypersensitivity to bovine gamma-globulin was produced by injecting 20 μg of the substance in the pierylated state (38 moles of pieryl/mole of bovine gamma globulin), in Freund's complete adjuvant into each hind footpad. In another group of guinea-pigs delayed hypersensitivity to a urea extract<sup>3</sup> of sheep red blood cells was produced by injecting 0.2 ml. of a mixture of equal volumes of 30 per cent sheep red blood cells and Freund's complete adjuvant into each hind footpad. 6-14 days after the injections of pierylated bovine gamma-globulin and 4-6 days after the injections of sheep red blood cells the popliteal and inguinal lymph nodes were excised. After the excisions skin tests showed delayed hypersensitivity to bovine gamma-globulin in thirty-four out of thirty-six animals in the first group, and to a urea extract of sheep red blood cells respectively in six out of eight animals in the second group.

Small fragments weighing about 5 mg each were prepared from individual lymph nodes and were cultured according to the method of Ferraresi and Halpern<sup>1</sup> with or without antigen (50 μg/ml. of bovine gamma-globulin or 15 volumes per cent of sheep red blood cell extract, respectively). The culture medium consisted of 80 per cent normal guinea-pig serum and 20 per cent guinea-pig spleen extract. The radii of cell migration were measured after 24 and 48 h of incubation. Antigen inhibited cell migration from fragments obtained from certain lymph nodes by 30-53 per cent as compared with cultures without antigen. The migration of both lymphocytes and macrophages was inhibited, but macrophages were affected to a greater degree. Bovine gamma-globulin (50 μg/ml.) did not inhibit the cell migration from lymph node explants of normal guinea-pigs or guinea-pigs injected with complete Freund's adjuvant. The sheep red blood cell urea extract stimulated the migration of normal cells slightly.

Only rarely were the cells of all inguinal and popliteal lymph nodes inhibited by antigen. This may be because

(1-4) From different guinea-pigs with delayed sensitivity; (a-c) different lymph nodes. Nos. 1 and 2 are animals sensitized with sheep red blood cells (the antigen added to the cultures was sheep red blood cell extract); Nos. 3 and 4 are animals sensitized with picrylated 38 bovine gamma-globulin (in cultures, with the bovine gamma-globulin).

\* Each figure represents the average migration radius of 5 to 8 explants.

of uneven distribution of the injected antigen and/or on variations in the stage of sensitization exhibited by individual lymph nodes at the time of sampling. Evidence was obtained by the immunocyto-adherence test<sup>4</sup> that lymph nodes, containing significantly increased numbers of cells carrying anti-sheep red blood cell antibody, were not sensitive to sheep red blood cell urea extract, although the guinea-pigs, from which the lymph nodes were excised, showed delayed hypersensitivity to a skin test with the same antigen.

To test for the presence of a soluble factor which could inhibit the migration of normal lymph node cells, we proceeded in two ways. (a) Explants from lymph nodes from sensitive animals were cultured in the same chamber with lymph node explants from normal animals or from animals injected with Freund's complete adjuvant. The explants were at least 5 mm from each other. Cell migration from the sensitive lymph node explants and from adjacent normal explants was inhibited in both cases to about the same degree in the presence of the specific antigen (Table 1). When no inhibition of cell migration occurred in the lymph node explants of a sensitive animal, then no inhibition was observed in the adjacent normal explants. (b) Culture media from bovine gamma-globulin-sensitive and control cultures were freed from cells by centrifugation, stored at  $-20^{\circ}\text{C}$  for 1-5 weeks and were then diluted 1:1 with fresh culture medium and added to the explants of control lymph nodes from guinea-pigs injected with adjuvant. The "inhibitory supernates" were obtained from cultures of explants containing Ag and taken from sensitive lymph nodes. "Control supernates" were taken from antigen-free cultures of sensitive and normal lymph nodes, and from antigen containing cultures of normal lymph nodes and of non-inhibited lymph nodes from sensitive animals. Cell migration of normal lymph node explants was inhibited 17 per cent to 54 per cent (average 37 per cent) in seven out of nineteen experiments in the presence of supernates from antigen sensitive cultures as compared with control supernates. This difference was significant ( $P < 0.02$ ). The migration inhibition in the donor cultures was 31 per cent to 53 per cent, with an average of 40 per cent. In nine of the remaining experiments inhibition was induced in normal explants ranging from 11 per cent to 40 per cent (average 23 per cent). These inhibitions were not significant at the 5 per cent level. Here the inhibition of migration in the donor cultures was between 22 per cent and 47 per cent, with an average of 30 per cent. In one experiment no inhibition of migration was conferred by supernate from sensitive culture inhibiting 22 per cent. In the other two experiments the supernates from antigen sensitive cultures stimulated 28 per cent and 29 per cent the migration of normal lymph node cells, although the media were taken from sensitive cultures inhibited 47 per cent and 34 per cent, respectively.

These findings confirm and extend to two additional antigens the results of Bloom and Bennett<sup>5</sup> and David<sup>6</sup>.

Our results indicate that the release of inhibitory material from sensitive cells in the presence of the antigen also occurs when the architecture of the lymph node is partially maintained.

That the induction of migration inhibition in normal lymph node cells by inhibitory supernates was not as strong and consistent as before<sup>5,6</sup>, could be caused by the dilution of the culture supernates from inhibited cultures with fresh medium. David<sup>6</sup> indicated that 1:5 dilutions of the inhibitory material were not effective in his system. In cultures of mixed lymph node explants, however, inhibition was conferred to normal explants, whereas David *et al.*<sup>7</sup> did not observe the same phenomenon in tests on capillary tubes filled with peritoneal exudate cells. It is likely that in the lymph node explants the variety and the number of interacting cells, especially of lymphocytes, are more complex than in the peritoneal exudates.

Our investigation leaves several points for further elucidation. (a) Why were several of the more remote local lymph nodes not sensitive to antigen? This may reflect the progression of the immune process through the lymphoid system. Similar observations have been made by Carpenter<sup>8</sup>, who also used the explant-culture method. There are at least two possibilities; either that these lymph nodes were not yet sensitive or that sensitive cells were no longer present in these lymph nodes. (b) The cells which were not inhibited by antigen were apparently unable to release inhibiting factor. This agrees with previous observations<sup>5,6</sup> that non-sensitive lymph nodes may not possess sufficient lymphocytes capable of secreting inhibitory factor. This is apparently not a sampling artefact, for all explants cultured from the entire node behaved similarly. (c) Finally, the relationship of sensitive and antibody-carrying cells to delayed skin reactivity needs further study.

## HAEMATOLOGY

## Surface Ultramicroscopy of Human Blood Cells

This communication describes the preliminary results of an investigation of the surface appearance of blood cells. Alterations in the surface contour of these cells were demonstrated using the Cambridge 'Stereoscan' electron microscope, which provides a three-dimensional view of the surface structure.

Early work<sup>1</sup> on individual cells, using the 'Stereoscan' electron microscope, has shown the different depression patterns from ameloblast processes on the surface of developing dental enamel in the manatee *Trichechus latirostris* and the monkey *Rhesus macacus*. More recently reports have illustrated the surface picture of simple and compound eyes<sup>2</sup>, details of the leg of a young shore crab<sup>3</sup> and the three-dimensional appearance of buccal squames and endothelial cells<sup>4</sup>.

Blood cells were prepared for examination by fixing sequestrenated whole blood or bone marrow in 0.5 per cent phosphate buffered glutaraldehyde (pH 7.4) (Lewis, S. M., personal communication), washing the cells in distilled water, and making a thin film on a small cover glass which was attached to the aluminium specimen stub. The specimens were covered with a layer of gold and palladium 500 Å thick to render their surfaces conducting. They were examined in the Cambridge 'Stereoscan' electron microscope and the micrographs recorded with a 20 kV scanning electron beam on Ilford 'HP3' film with an exposure time of 40 sec.

The normal red blood cell appeared exactly as would have been expected from the appearance of unstained fresh blood under the light microscope, that is, as a biconcave disk 7–8  $\mu$  in diameter (Fig. 1). The surface of the majority of red cells was relatively uniform and smooth, even at magnifications of 115,000. In patients with a reticulocytosis, a proportion of red cells about the same percentage as the percentage of reticulocytes, had a slightly more granular surface than usual (Fig. 2). These findings were broadly in agreement with those of Danon and Marikovsky<sup>5</sup>, who studied separated red cell membranes with a transmission electron microscope. In blood

Fig. 1. Normal red blood cells. Note the platelet lying in the concavity of a red cell in the foreground. ( $\times 2,850$ .)

Fig. 2. Reticulocyte from a case of systemic lupus erythematosus with haemolytic anaemia. The central concavity is much less pronounced and much of the red cell surface is finely granular. ( $\times 12,500$ .)

Fig. 3. Red blood cells showing patchy denudation of the nuclear membrane from a case of idiopathic thrombocytopenic purpura following splenectomy. ( $\times 4,850$ .)

from patients who had undergone a splenectomy, many red cells showed denudation of the outer cell membrane in small, irregular patches, often with detached membrane around the margin of such areas (Fig. 3). This is probably an ageing process.

Various pathological red blood cells, such as hypochromic cells, spherocytes, macrocytes, elliptocytes, poikilocytes, schistocytes, sickle cells and target cells, were identified with relative ease. For example, target cells were obtained from cases of thalassaemia, liver disease and steatorrhoea and from patients after splenectomy. Regardless of the underlying disease process, the target cells were of two types; they showed either a central hemispherical protrusion (Fig. 4) or a roughly linear protrusion extending across the cell almost as far as the peripheral cell thickening (Fig. 5). The majority

of cells in cases of sickle cell anaemia were considerably elongated, a linear fold extending along the entire long axis of the cell (Fig. 6). The surface of pathological red blood cells at high magnifications did not vary much from normal in the majority of cases. In certain cases of haemolytic anaemia and dyshaemopoietic anaemia, large pores were noted in the membrane of some red cells. This phenomenon is being investigated further. The complement holes described in the membranes of red cells from cases of paroxysmal nocturnal haemoglobinuria<sup>6</sup> could not be seen. Such holes have been reported to have mean diameters of about 103 Å—the resolution of the 'Stereoscan' microscope is generally 200 Å.

White blood cells were examined in preparations of nucleated cell concentrates of blood and of bone marrow. The surface appearance of white cells fixed by glutaraldehyde in suspension was less striking than that of red cells. Granulocytes were approximately 10  $\mu$  in diameter, were covered with multiple pseudopodial projections, and had smooth surfaces. Lymphocytes were 8–9  $\mu$  in diameter,

Fig. 4. Target cell from a case of thalassaemia major. ( $\times 11,500$ .)

Fig. 5. Target cell from a case of phenacetin-induced haemolytic anaemia. ( $\times 11,000$ .)

Fig. 6. Sickle cell. Sickle cell anaemia. ( $\times 10,000$ .)

Fig. 7. Lymphocyte from normal blood. ( $\times 9,500$ .)

spherical, and with a rough, "shaggy" surface (Fig. 7). Monocytes were 12–15  $\mu$  in diameter, irregular in shape, and with a rough surface similar to that of the lymphocyte. White cell precursors were remarkably uniform and featureless in surface appearance, varying only in size.

Platelets were irregular in outline, with no characteristic surface appearances. Megakaryocytes in preparations from bone marrow were readily identified as large cells 30–50  $\mu$  in diameter with evidence of active platelet formation on their surface (Fig. 8). The smallest platelets appeared to be completely spherical and smooth: only large platelets which were almost completely detached from the cytoplasm of the megakaryocyte showed the irregular outline described already.

We thank the Cambridge Instrument Company for access to their instrument, and Miss Farrow for her tech-

## Haemoglobin Types in Deer

HAEMOGLOBIN types have been examined in only a few species of deer. Single fractions without variants have been found in chital deer (*Axis axis*) and Indian muntjac (*Muntiacus muntiacus*)<sup>1</sup>, red (*Cervus elephas*) and fallow deer (*Dama dama*)<sup>2</sup>, and in sika (*Cervus nippon*) and barasingha deer (*Cervus duvanceli*)<sup>3</sup>. Haemoglobin which separates electrophoretically into one to three fractions has been found in white-tailed deer (*Odocoileus virginianus*)<sup>3-6</sup>. We have examined the haemoglobin types in feral British deer and single samples of Père David (*Elephurus davidianus*), chital and barasingha deer by paper and Poulik's discontinuous buffer starch gel electrophoresis<sup>7</sup>, pH 8.8, and by alkali denaturation<sup>8</sup>. The numbers of these species are listed in Table 1.

Table 1

Deer species	No. examined
Red, <i>Cervus elephas</i>	32
Sika, <i>Cervus nippon</i>	44
Barasingha, <i>Cervus duvanceli</i>	1
Fallow, <i>Dama dama</i>	62
Roe, <i>Capreolus capreolus</i>	80
Chinese muntjac, <i>Muntiacus reevesi</i>	40
Père David, <i>Elephurus davidianus</i>	1
Chital, <i>Axis axis</i>	1
Chinese water, <i>Hydropotinae inermis</i>	21

The electrophoretic mobilities of haemoglobin from red, sika, barasingha, Père David and chital deer are identical in the methods used. Fallow deer haemoglobin moves faster than these, with roe haemoglobin lying between fallow and *Cervus* species. All these species yield a single haemoglobin fraction, and no variants were found among them except for a single fast moving component in a roe fawn replacing the normal haemoglobin of this species.

The Chinese muntjac (*Muntiacus reevesi*) has a polymorphic haemoglobin, the different samples examined having two or three fractions. The different patterns obtained were separable as two slower moving fractions occurring together provisionally identified as type A, and two faster moving fractions as type B, the faster moving fraction of type A corresponding in mobility to the slower moving fraction of type B. A third pattern of separation was also found after starch gel electrophoresis in which haemoglobin fractions of all three mobilities were found together. Electrophoresis of a mixture of types A and B yielded a pattern indistinguishable from the naturally occurring three bands. Assuming that the distribution of the genes from the two forms A and B are allelic, the presence of three bands would appear to represent the heterozygous form AB.

Determination of the gene frequencies according to Wiener and Vaisberg<sup>9</sup> yields

	Type A	Type AB	Type B	Total
No. of samples	11	22	7	40
Proportion per cent	27.5	55	17.5	100
Frequency of gene A = 0.55				
Frequency of gene B = 0.45				

Incidence in sample examined if AB is the heterozygote of AA and BB

	Expected	Observed
AA	12	11
AB	19.4	22
BB	8.5	7

$\chi^2 = 0.494$ ,  $P = 0.5$  supporting the suggestion that types A and B are allelic.

In eighteen of the Chinese water deer (*Hydropotinae inermis*) the haemoglobin moved as a single fraction provisionally identified as A, with the same mobility as the *Cervus* species. A second, slow moving, minor component (B) was present in three of them. No example of the second component occurring alone was seen, but calculation of the gene frequencies, assuming them to be allelic, gives type A as 0.92 and type B as 0.07.

Samples from all species showed more than 50 per cent resistance to alkali denaturation. All blood samples examined except for one muntjac foetus (type B) were taken from adult or late juvenile animals and no evidence was found for a foetal haemoglobin component. The

Fig. 1. Reeve's muntjac haemoglobin. Poulik's discontinuous starch gel electrophoresis, pH 8.8.

sickling phenomenon in 0.9 per cent saline solution was demonstrated in red, sika, barasingha, fallow, roe and muntjac. Père David and chital deer red cells were not examined for this phenomenon. None of the twenty-one samples of Chinese water deer red cells sickled in physiological saline or in 2 per cent sodium metabisulphite.

The sika samples examined included two of the Manchurian variety of the species. The haemoglobins of these were indistinguishable from the type species.

As the haemoglobin of the Indian muntjac was found by Naik<sup>1</sup> to separate into one fraction only, it appears likely that the muntjacs feral in south-east England are of the Chinese species. Genetic admixture with Indian muntjacs which escaped from parks many years ago is a possibility and haemoglobin analysis may provide a point of taxonomic separation of the species. It may also help in strain separation of the Chinese water deer, but appears to be of no value among the genera of larger deer.

## GENETICS

### Another XYY Phenotype

ON seeing the webbed neck of a 24 year old mentally retarded male, one of us (M. B.) was prompted to question the cytogenetic sex. The man in question was of average height, well built, with adult genitalia, descended testes, and male hair distribution. The inguinal lymph nodes were palpable. He was living in an institution among mental defectives and had a history of suspected arson, seizures, emotional disturbances and familial mental retardation of marginal degree.

Chromosomes were counted in fifty-four, and karyotypes were assembled from twenty-two, metaphases of cultured leucocytes<sup>1</sup> stained lightly with orcein and photographed by phase microscopy. The Y and G group chromosomes were further distinguished by shadowing with platinum-carbon<sup>2</sup> and by autoradiography of chromosomes labelled with tritiated thymidine 3 h before mitoses were arrested with colchicine<sup>3</sup>.

Ninety per cent of the cells contained forty-seven chromosomes. The karyotype showed an extra small acrocentric that fitted morphological criteria for the Y chromosome<sup>4</sup>. The aneuploidy of the few cells with more or less than forty-seven chromosomes was variable and unrelated to the sex or G group chromosomes. One endoreduplicated metaphase contained ninety-four chromosomes.

Shadowing (carried out by courtesy of Dr M. R. Edwards) emphasized the satellite distinctions, and autoradiography the differential labelling pattern of the Y

Fig. 1. Three partial karyotypes of G group and Y chromosomes. (a) Stained with aceto-orcein; (b) shadowed with platinum-carbon; (c) autoradiographed after 4 h of exposure to tritiated thymidine.

and G group chromosomes (Fig. 1). Relative asynchrony in labelling of the two Y chromosomes occurred, as has been noted before<sup>5,6</sup>.

This phenotype is unique among the twenty-five or so XYY genotypes recorded for his striking webbed neck. Its clinical significance is not clear, however, other than to trigger associations, because its concomitance in "male Turner's" syndrome is usually accompanied by a normal male karyotype<sup>7</sup>. Nor is there much likelihood of our patient having been a cytogenetic Turner's mosaic, because recorded XO/XYY phenotypes are female<sup>8,9</sup>.

Our case adds to the variable phenotype presented by XYY genotypes, and a recent dissenting report of synchronous labelling of YY chromosomes in two normal males<sup>10</sup> suggests that phenotypic differences are reflected in a variable autoradiographic pattern. Reference to the phenotype as the "YY syndrome" is, indeed, inadvisable<sup>11</sup>.

## Heredity of Two Types of Normal Colour Vision

THE anomaloscope is used to diagnose red and green colour blindness and its four or six sub-types. In the apparatus the lower half of a circular plane is illuminated by a yellow light of wavelength 589 m $\mu$ , and in the upper half red (670 m $\mu$ ) and green light (546 m $\mu$ ) are mixed. It is possible, by changing the proportion of red and green illumination, to make the two halves look the same; the proportion of red and green lights required is called the Rayleigh equation, which is accepted by individuals with normal colour vision, but colour blind people react in different ways. On the anomaloscope which I used (model II, Schmidt and Haensch, Berlin) it is possible to change the wavelength of the monochromatic yellow light to make it more and more yellow green, or more and more orange, while the red and green lights are shifted in a similar manner. Rayleigh equations can be found for these wavelengths. I have built up a system of nine equations with the yellow light varying from 574 m $\mu$  to 603 m $\mu$ .

When these nine equations are recorded for males it appears that some of them show a series of smaller values, while others show a series of larger values. There might be some overlapping in places, but on the whole the males can be divided into two groups, with two normal properties, which I have called protopia and deuteropia, denoted by P and D (both for the property and for the gene which is supposed to be responsible for the property). With the same anomaloscope it can be shown that the protopic individuals have their greenpoint (when they see green and not yellow or blue) at about 515 m $\mu$ ; the others have their greenpoint at 525 m $\mu$ .

Females can be divided into the same two groups, but about fifty out of a hundred of them show a third type of reaction. They behave as deuteropics in the orange region (the D dominates, but not completely), and as protopics in the green tinted region (the P dominates, but not completely).

I propose that these properties derive from hereditary factors in the X chromosome, from two mutant allelomorphs in one cistron. This would mean two genotypes in the male, P and D, with frequencies—which are also the gene frequencies in the population—of 60 per cent and 32 per cent to 8 per cent, which is the frequency of colour blindness in males, and there would be the two phenotypes, protopia and deuteropia. In females there would be three genotypes, PP, PD and DD, and three phenotypes, protopia, intermediary (supposed to be the heterozygotes P/D) and deuteropia. The heterozygous group has a greenpoint at about 520 m $\mu$ , with some overlapping with the other groups of greenpoints.

Because of the intermediate nature of the reactions of the supposed heterozygous group, diagnosis might not be so easy for females as for males. It is made more difficult—it is almost impossible to be accurate—in the group, expected to be about 15 per cent of all females, who are heterozygous for the genes for colour blindness. These females (eight (12) groups with P or D in the one X chromosome and one of the four (6) genes for colour blindness in the other X chromosome) show atypical reactions with respect to the nine equations, atypical reactions which suggest colour blindness.

Results of family examinations are given in Tables 1 and 2.

These two tables show agreement with the hypothesis discussed previously for the mode of inheritance. There was one exception: a P "father" and D "daughter". I cannot be sure that the determinations are correct, but the most likely explanation is that the P male is not the true father to this eldest daughter, although he could be the father to the younger daughter, who was PD. Even with this exception the two tables are convincing evidence of the validity of my hypothesis.

Table 1. THE P AND D DIAGNOSES FOR MOTHERS AND THEIR SONS

Mothers	Sons	
	P	D
20 P mothers	31	
27 PD mothers	26	21
8 D mothers		11

Table 2. THE P, PD AND D DIAGNOSES FOR GROUPS OF PARENTS AND THEIR DAUGHTERS

Parents	Daughters	
	P	D
21 P $\times$ PP	38	
15 P $\times$ PD	10	15
1 P $\times$ DD		15
8 D $\times$ PP		4
8 D $\times$ PD		8
6 D $\times$ DD		9

Based on these facts, I suggest that these hereditary factors have one locus in one cistron in the X chromosome, with two mutants for normal colour vision and four (6) for defective colour vision.

## No Simple Pattern of Inheritance in Ability to smell Solutions of Cyanide

IN 1950, at the Cold Spring Harbor Symposium on the origin and evolution of man, Mourant commented: "It is most important that more new markers be sought and found for the human chromosomes." As an example of a possible new marker he remarked that: "One person out of four fails to smell hydrogen cyanide, a proportion suggesting a balanced polymorphism".

Since then the ability to detect the odour of hydrogen cyanide has been studied in populations in Europe<sup>2</sup>, Africa<sup>3</sup>, India<sup>4</sup>, Japan<sup>5</sup> and Australia<sup>6</sup> with some evidence of differences in the frequency of "non-smellers". Kirk and Stenhouse<sup>6</sup> and Fukumoto *et al.*<sup>5</sup> investigated families, and suggested that the trait "inability to smell hydrogen cyanide" was inherited as a sex linked recessive, but their families showed some exceptions to the expected results of that hypothesis<sup>7</sup>. Huser *et al.*<sup>2</sup>, by similar studies, showed that this trait is neither recessive nor sex linked, and they concluded that it is inherited as a dominant, probably autosomal.

Published reports on the detection of hydrogen cyanide odour are based on a variety of methods of detection and arrangements for presenting the gas to the subject. These variations have made exact comparison between the various reports impossible.

In an attempt to evaluate further the trait for detection of this odour, we have carried out a series of studies using a serial dilution technique similar to that of Harris and Kalmus<sup>8</sup> for phenylthiocarbamide taste testing except the solutions are smelled rather than tasted. A solution of 10 g of potassium cyanide in 100 ml. of distilled water was diluted by a factor of four in eleven serial steps. Of the resulting twelve solutions the strongest was a million times more concentrated than the weakest. This range of concentrations has been found to cover the sensitivities of most adult humans in our test system.

In the test procedure, the subject was presented with a rack of twelve 1 in. diameter, stoppered, test-tubes. Eleven contained 50 ml. of a serial dilution, and one identical tube contained distilled water. The subject was instructed to smell the water and then each of the eleven tubes in succession and report if the tube smelled like the water or smelled different. The tubes were presented to the subject in order from the most dilute to the most concentrated. The first tube which provoked a response difference from water was considered to be the threshold and its rank is used as the score in tabulation and calculation.

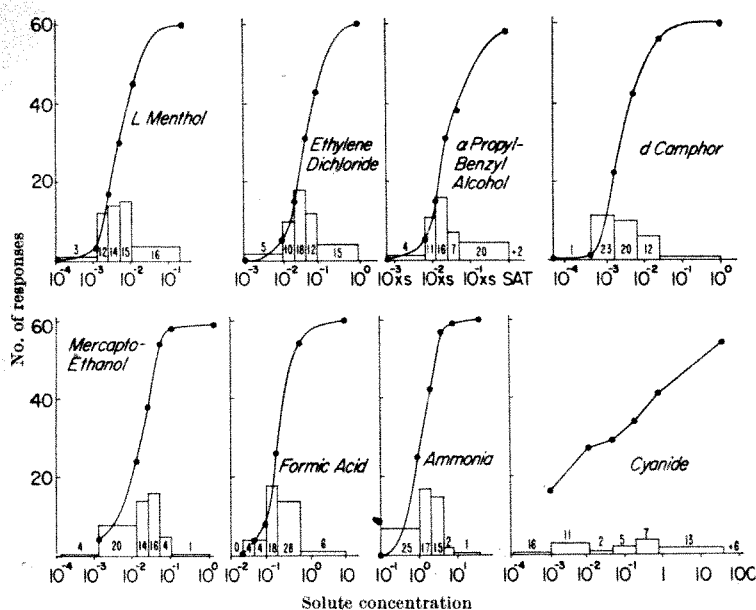

Fig. 1. The distribution of thresholds of detection of odour for water solutions of eight compounds in sixty unrelated adults.

A pretest of the system on sixty healthy adults showed (Fig. 1) that the distribution of the threshold of hydrogen cyanide was different from a wide variety of other compounds tested in a similar manner. Hydrogen cyanide had a much wider range of thresholds and the distribution was trimodal rather than unimodal. The unimodal distribution of "good smellers", "fair smellers" and "non-smellers" gave a perfect fit to a binomial distribution assuming an autosomal pair of additive alleles with the non-smell gene having a frequency of 0.316. There was no evidence for any difference between the sexes in the

Fig. 2. (A) The distribution of perception threshold for hydrogen cyanide odour in 1,515 boys and 1,370 girls aged 10-18 yr. (B) The distribution of perception threshold for hydrogen cyanide odour in eighty-six pairs of parents. DNS does not detect a smell in 10 g/l. of potassium cyanide. □, Male; ○, female.

frequency of the phenotypes, which suggested that sex linkage was not involved.

The test system was then used to collect threshold data on 2,885 school children of age 10-18 yr, and all of European ancestry. Data were available for assigning them to sibships. The thresholds of the children were distributed similarly to the pretest series (Fig. 2A). There was a trimodal distribution with modes at solution concentrations of  $10^{-6}$ ,  $10^{-3}$  and  $10^{-1}$  of potassium cyanide/l. or more. There was no overall difference in the distribution of males and females as would be predicted on the basis of sex linkage. The apparent excess of males in both the end groups may be a function of the differences in age distribution of the sexes with respect to age in the school population studied because of a decrease in frequency of girls in the older age groups. There was also a significant difference in the distribution of thresholds with respect to age which may be compounded with the differences between the sexes of the modes of the sensitive group.

The population distribution could not be fitted as a genetic equilibrium, if there were only two alleles at one locus. Assuming that the three modal classes represent genotype groups, rather confused by other factors, a variety of autosomal additive models involving three alleles or two independent loci will fit it very well.

Eighty-six pairs of parents were also tested (Fig. 2B); their distribution was significantly different from that of the children. The fathers showed a decrease in frequency of "good smellers" and a large increase in the "non-smellers" group. The frequency of non-smeller mothers was about the square of the frequency of non-smeller fathers as would be predicted by the hypothesis of simple sex linked recessive inheritance. Such a hypothesis does not explain the "fair smeller" modal group and is not compatible with the distribution of the thresholds of the children.

Further evidence about the genetics of hydrogen cyanide thresholds can be obtained from the limited segregation data provided by eighty-six families (Table 1). These data indicate that there is no simple segregation pattern and that the children are distributed within families roughly in proportion to the population distribution rather than in relation to parental phenotypes.

The difficulty in finding compatible genetic hypotheses to explain both parent and child threshold distributions and the lack of expected genetic segregation patterns in the different classes of sibship raises a question about the existence of any genetic component in the control of hydrogen cyanide odour threshold. An examination of the correlations of thresholds between different types of related individuals showed little correlation even between twins of the same sex (Table 2). The only significant positive correlations were between like sex siblings and there was a significant negative correlation between

Table 1. SEGREGATION OF THE ABILITY TO SMELL HYDROGEN CYANIDE IN EIGHTY-SIX SIBSHIPS CONTAINING 156 CHILDREN

Parents		Children		
Father group	Mother group	Group 1	Group 2	Group 3
1	1	26	5	2
2	1	14	1	2
3	1	28	11	7
1	2	15	3	0
2	2	9	8	2
3	2	1	1	3
1	3	3	3	0
2	3	0	0	1
3	3	8	2	1

Group 1 detects less than  $16^{-4}$  g/l. of potassium cyanide; group 2 detects  $10^{-2}$  but not  $10^{-4}$  g/l. of potassium cyanide; and group 3 does not detect  $10^{-2}$  g/l. of potassium cyanide.

Table 2. CORRELATION OF HYDROGEN CYANIDE ODOUR THRESHOLD SCORES IN RANDOM CHILDREN, SIBLINGS AND PARENTS

	No.	Correlation
Random pairs of children	240	0.03
Consecutive siblings	264	0.07
Mother and daughter	72	0.05
Father and son	59	0.34
Same sex twins	20	0.30
Male sib pairs	209	0.20**
Female sib pairs	188	0.23**
Male-female sib pairs	210	-0.43**

\*\* Significant at 0.01

siblings of different sexes. These results are not compatible with a simple Mendelian hypothesis. The pattern of correlations was suggestive of a familial environmental factor affecting males differently from females. Possible environmental factors that are compatible with this type of distribution are tobacco smoking and contact with chemicals such as fertilizers and pesticides.

The existence of some genetic component similar to that in other complex physiological traits such as blood pressure or blood sugar concentration is suggested by the increase of the correlation coefficients from siblings through same sex siblings to same sex twins. This is, however, confounded with the high degree of correlation between members of the same sex in the same family.

The threshold for hydrogen cyanide odour does not seem to be a simple, segregating, genetically controlled trait. A similar conclusion has been independently reached by Kirk (personal communication). The genetic proportion of the control of the threshold seems to be small compared with the total variation. Investigation of the hydrogen cyanide odour threshold seems to be of limited use in genetic studies of populations or families, because of the important part that age and environmental factors play in its control.

## CYTOLOGY

### Genesis of Hassall's Corpuscles

HASSALL's corpuscles, a characteristic structure of the thymus, are composed of acidophilic concentrically arranged cells. Only two hypotheses<sup>1,2</sup> for the genesis of these corpuscles account for the epithelioid character of their cells, their extensive branching<sup>3</sup>, the presence of a lumen at different stages of their development, and the presence of vascular elements within them. If the Hassall's corpuscles have a vascular origin<sup>4,5</sup>, this suggests that they are derived from the occlusion of capillary segments followed by inspissation of their contents, and necrosis of the vascular endothelium with proliferation of the neighbouring epithelium to form their typical "onion-like" structure. The other hypothesis<sup>3,6</sup> suggests that Hassall's corpuscles develop from persistent thymopharyngeal ducts lined with epithelium and that the frequent vascular elements are derived from the associated venules. Our evidence—obtained during an investigation of antigen localization in organs—supports the blood vessel origin of Hassall's corpuscles.

Polymerized flagellin labelled with iodine-125, a protein constituent of the flagella of *Salmonella adelaide*, was injected intravenously or into the hind foot-pads of 10-12 week old Wistar albino rats of both sexes in a quantity of 10 µg. Details of the procedures for both the preparation and iodination of polymerized flagellin are published elsewhere<sup>7</sup>.

The rats were X-irradiated at 235 kV, 15 m.amp, half value layer of 1.0 mm of copper, at a dose rate of 68 rads/min 1 day before the injection of polymerized flagellin.

To prepare autoradiographs, the thymus was fixed in 10 per cent formalin and histological sections, 5µ thick, were prepared by the paraffin method. Sections were dipped in Kodak 'NTB/2' emulsion, exposed for 60 days, developed and stained with methyl green and pyronin.

The animals were divided into three groups: (a) unirradiated; (b) sub-lethally irradiated with 450 r.; and (c) lethally irradiated with 950-16,000 r. Results of the examination of these autoradiographs of the thymus, for localization of polymerized flagellin, are shown in Table 1.

Table 1. LOCALIZATION OF LABELLED POLYMERIZED FLAGELLIN IN AUTORADIOGRAPHS OF THE RAT THYMUS

X-ray* dose	No. of † rats	Hours after injection of labelled polymerized flagellin	
		3	48-72
None	7	Label in wall and lumen of blood vessels in all rats	No label in any rat
450 r.	7	Label in wall and lumen of blood vessels in all rats	Occasional Hassall's corpuscle labelled in three rats
950-16,000 r.	11	Not done	Label in the wall and lumen of many blood vessels and Hassall's corpuscles in all rats.

\* Rats were irradiated 1 day before the injection of the labelled material.

† This refers to the number of rats in each sample.

Autoradiographs of the thymus from groups a and b, 3 h. after injection of polymerized flagellin, showed that the label was restricted to the wall and lumen of blood vessels (Fig. 1). Two or three days after injection of antigen there was no detectable label in any thymus from seven unirradiated rats that had received labelled polymerized flagellin either intravenously or into the hind foot-pad. In three of seven similarly injected rats that were irradiated with 450 r., label was confined to occasional Hassall's corpuscles (Fig. 2). In all eleven rats exposed to radiation between 950 and 16,000 r. and examined 1 or 2 days after injection of antigen, label was found in vessels ranging from those with a patent lumen through a series of intermediate stages to the developed Hassall's corpuscle (Fig. 3).

The suggestion that the Hassall's corpuscles are derived from vascular elements is supported by my observations on localization of protein labelled with iodine-125 and indirectly by the observations of vascular changes in irradiated animals<sup>8</sup>. The small vessels in a section of skin from rats exposed to large doses of X-ray were found to be fewer in number than in normal rats and showed varying degrees of vascular occlusion not normally seen. Thus the larger doses of radiation induced both a greater incidence and an increase in the rate of change in the endothelium that led to occlusion. These effects, in turn, would lead to the trapping of more antigen in more vessels. Treatment with agents, such as X-ray or cortisone<sup>2</sup>, which cause thymic involution increased the uptake of carbon particles by perivascular macrophages. A process such as described by the proponents for the blood-vessel origin of Hassall's corpuscles therefore might occur with greater frequency and speed after irradiation.

The proposal that Hassall's corpuscles arise from persistent thymo-pharyngeal ducts, with the accidental inclusion of endothelial elements<sup>3,7</sup>, cannot account for the presence of polymerized flagellin in these structures. It does not explain how this protein gets from the blood

Fig. 1. Section of rat thymus 3 h after intravenous injection of polymerized flagellin labelled with iodine-125. Note the label associated with the patent blood vessel.

Fig. 2. Section of thymus taken 2 days after foot-pad injection of polymerized flagellin labelled with iodine-125 into a rat exposed to 450 r. Note the label directly over typical Hassall's corpuscles.

Fig. 3. Section of thymus taken 2 days after foot-pad injection of polymerized flagellin labelled with iodine-125 into a rat exposed to 8,000 r. Note that the label is associated with an occluded vessel which terminates in a typical Hassall's corpuscle.

vessels to the corpuscle. The ducts are not patent in adult life, and the polymerized flagellin is seen only in association with the walls of patent vessels (not lined with epithelium), in the Hassall's corpuscles, and in the intermediate stages (Figs. 2 and 3).

Hassall's corpuscles in the thymus could represent no more than a common end-product of diverse origin. Development around an occluded vascular segment in this case would represent only one way in which the

corpuscle develops. The present evidence and observations from thymuses of patients with systemic lupus erythematosus<sup>6</sup> strongly suggest a vascular origin for this structure.

## BIOCHEMISTRY

### Steroids of Invertebrates: Production of Oestrogens by an Accessory Reproductive Tissue of the Slug *Arion ater rufus* (Linn.)

A PREVIOUS communication<sup>1</sup> described the endogenous production of 11-keto-testosterone, testosterone and 17 $\alpha$ -hydroxyprogesterone during the *in vitro* incubation of the eggs of *Arion ater*. The present study concerns the *in vitro* production of C<sub>18</sub> steroids from endogenous precursors by an accessory reproductive organ of this animal, the bursa copulatrix or spermatheca gland. The function of the spermatheca is believed to be storage of sperm acquired during copulation<sup>2</sup>.

Spermatheca glands containing sperm (1.62 g wet weight) were obtained from ten adult animals and incubated *in vitro* for 4 h; the conditions of incubation and methods adopted for steroid isolation and purification were similar to those described previously<sup>1</sup>. Steroid fractions obtained after repeated thin-layer purification on silica gel GF<sub>254</sub> were chemically modified by derivative formation, and the products submitted to gas chromatographic investigation. All gas chromatographic data were obtained with an 'F and M 400' biomedical gas chromatograph using a 2 per cent 'XE-60' column; eluted substances were detected by hydrogen flame ionization. Quantitative assessments of the steroids produced were based on their individual mass/peak area response graphs.

After *in vitro* incubation of the spermatheca gland tissue and (presumably) its sperm content, no detectable amounts of progesterone, pregnenolone, 17 $\alpha$ -hydroxyprogesterone, 17 $\alpha$ -hydroxypregnenolone, testosterone, androstenedione or dehydroepiandrosterone were revealed by gas chromatography. Two substances formed during the incubation, however, were shown to be identical with authentic oestrone and oestradiol-17 $\beta$ .

The presence of oestrone was tested as follows. Acetylation afforded a product the *R<sub>F</sub>* of which was identical with that of oestrone acetate; gas chromatography of the acetate alone or mixed with authentic oestrone acetate gave a single peak of the correct retention value; alkaline hydrolysis and sodium borohydride reduction yielded a substance which appeared as a homogeneous Turnbull blue positive spot, the *R<sub>F</sub>* of which was identical with that of authentic oestradiol-17 $\beta$ .

For oestradiol-17 $\beta$  the following procedure was adopted. The substance obtained after acetylation had an  $R_F$  value which corresponded with that of oestradiol-17 $\beta$  diacetate; individual or mixed gas chromatography with authentic oestradiol-17 $\beta$  diacetate gave retention data which suggested the identity of the two substances; alkaline hydrolysis and chromic acid oxidation furnished a product the similarity of which to authentic oestrone was indicated on the basis of a single Turnbull blue spot of the correct  $R_F$  value. Oestrone and oestradiol-17 $\beta$  were produced in amounts (uncorrected for losses incurred during processing) of 115 and 77  $\mu\text{g/h/g}$  of tissue, respectively.

We have found that the two naturally occurring mammalian  $C_{18}$  steroids, oestrone and oestradiol-17 $\beta$ , are also present in an accessory reproductive tissue of this invertebrate. Hitherto no  $C_{18}$  steroids have been chemically demonstrated as occurring in an invertebrate phylum. It is yet to be determined whether  $C_{18}$  steroids, which have clearly defined oestrogenic activity in vertebrates, also participate in invertebrate reproductive physiology. The fact that no precursors of oestrogenic steroids were detectable might be a result of one or all of the following alternatives. Spermatheca tissue may selectively concentrate oestrogens produced at other sites; the turnover of precursors may be very rapid so that end-products only are detectable; immediate precursors such as androstenedione and testosterone may be produced at other sites, concentrated selectively by the spermatheca, whereupon oestrogen synthesis occurs with rapid disappearance of the substrate.

### Neutron Activation as a Means of Detecting Phosphoryl Peptides

AMINO-ACID sequences about "active-centre" residues, which react with organophosphorus inhibitors or which are the site of attachment of phosphate in phosphoryl-enzyme intermediates, have been a subject of interest in

recent years<sup>1</sup>. In these sequence studies inhibitor or reactant labelled with phosphorus-32 is generally used and the peptides, after degradation of the protein, are detected and distinguished from other ninhydrin-positive material by their radioactivity. Sanger and co-workers<sup>2-5</sup> have developed a method for the determination of sequence about a labelled residue in which the use of ninhydrin is eliminated and considerably less material is required. In their work the labelled protein is subjected to partial acid hydrolysis and the phosphoryl peptides are separated by high voltage electrophoresis on paper. The pattern of peptide bands detected by autoradiography is characteristic of the amino-acid sequence present in the protein.

This note reports a new procedure in which the protein is reacted with unlabelled reagent, the phosphorylated protein hydrolysed and the peptides separated by electrophoresis. The peptides are then subjected to neutron irradiation on paper, whereby the phosphorus is made radioactive and can thus be detected by autoradiography or scanning techniques. This procedure avoids any inconvenience of working with the radioactive form of the reagent, and yet utilizes the advantages of labelling with phosphorus-32 in comparing the pattern of phosphoryl peptides with that from known sequences.

In the test experiments chymotrypsin and subtilisin which had been inhibited by DFP (diisopropylphosphoryl-fluoridate) to yield the DIP (diisopropylphosphoryl)-enzymes were used, together with pepsin, a natural phosphoryl protein. Samples of the phosphoryl proteins were partially hydrolysed with acid (6 normal hydrochloric acid at 100°C for 30 min) and the resulting peptides separated by electrophoresis on Whatman 3 MM paper (pH 3.5, pyridine-acetic acid, 40 V/cm, 2h). After drying, marker spots of serially diluted *O*-phosphorylserine in the range 4.0–0.02  $\mu\text{g}$  phosphorus/cm<sup>2</sup> were applied to the paper. The electrophoretogram was rolled between aluminium foil and sent to the Australian Atomic Energy Commission Research Establishment, Lucas Heights, where it was irradiated with a neutron flux of  $3 \times 10^{12}$  neutrons/cm<sup>2</sup>/sec for 4 h. A longer time of irradiation was not recommended by the A.A.E.C. as the paper is liable to damage and may be difficult to unroll. After irradiation autoradiography was carried out using Kodak medical X-ray film.

Autoradiographs completed within 2 days of irradiation showed a uniformly dark background caused by activation of impurities in the paper. The main impurity was apparently sodium which had been activated to

Fig. 1. Autoradiograph of sections of electrophoretogram after neutron irradiation. Top section: hydrolysate of DIP-chymotrypsin; the origin is on the left and the band on the extreme right is *O*-phosphorylserine. Middle section: comparison of hydrolysates of pepsin (top) and DIP-subtilisin. Bottom section: marker spots of *O*-phosphorylserine; the concentration of phosphorus from left to right is 4.0, 0.8, 0.4, 0.2, 0.1, 0.04 and 0.02  $\mu\text{g}$  phosphorus/cm<sup>2</sup>.

sodium-24, with a half-life of 15 h, so that 4 days after irradiation the sodium-24 had very largely decayed and, on an autoradiograph prepared after that time, bands were visible against a lighter background. Carbon, hydrogen, oxygen and nitrogen would not be expected to yield any significant amount of radioactive material on neutron bombardment under the conditions used, and sulphur did not give rise to sulphur-35 because no darkening on the autoradiograph was observed in the position of cysteic acid containing peptides derived from oxidized insulin. The radioactive bands were later cut out and counted in a scintillation counter at various times over 2 weeks; they showed a half-life of 14.3 days which is characteristic of phosphorus-32.

Fig. 1 shows an autoradiograph of sections of the electrophoretogram; the film and electrophoretogram were in contact for 10 days starting 6 days after the irradiation. The patterns of phosphoryl peptides obtained from DIP-chymotrypsin and DIP-subtilisin are the same as those previously observed using  $^{32}\text{P}$ -DFP and are characteristic of the sequences Gly.Asp.SerDIP.Gly<sup>2</sup> and Thr.SerDIP.Met.Ala<sup>3</sup> respectively. Pepsin is reported<sup>6</sup> to contain the sequence Thr.SerP.Glu, but the electrophoretic pattern of phosphoryl peptides obtained after partial acid hydrolysis has not been examined previously. Approximately 0.8 mg of the phosphoryl protein hydrolysates was applied over 2 cm for separation on the electrophoretogram and a concentration equivalent to 0.04  $\mu\text{g}$  phosphorus/cm<sup>2</sup> was clearly visible.

While in the example above peptides were produced by partial acid hydrolysis, the procedure could be applied to an enzyme hydrolysate of a suspected phosphoryl-enzyme intermediate isolated from an enzyme catalysed reaction. Study of such peptides would enable determination of the stability of the phosphoryl bond. If a metallo-enzyme is used in such experiments the metal may give rise to a radioisotope in the neutron flux, but such radioisotopes should be distinguishable from phosphorus-32 by their decay characteristics.

A disadvantage of this technique is that irradiation could cause destruction of the amino-acids and so, unlike the work starting with the radioactive form of a reagent, the peptides, once activated, could not be used for further determination of structure. Detection could be performed on marker strips, however, as is normal for staining techniques. Sensitivity of detection would be enhanced by the use of a chromatogram scanner, but even by autoradiography it is at least ten times better than molybdenic acid sprays<sup>7</sup> and is independent of the chemical form of the phosphate. The use of neutron activation in the characterization of small quantities of nucleic acids has been reported by Murray and Offord<sup>8</sup>.

### Cardiac Monoamine Oxidase in Rat

THE monoamine oxidase (MAO) of the rat heart exhibits the unusual property of increasing in activity with increasing age and weight<sup>1</sup>. This property is not shared by the liver or brain; these organs reach a maximum MAO activity early in life and presumably maintain these levels

Table 1. DEVELOPMENT OF MAO ACTIVITY IN LIVER AND BRAIN OF MALE AND FEMALE RATS

Age in weeks	Liver		Brain	
	Male	Female	Male	Female
2	20.2 (17.5-23.0)	24.7 (23.7-24.9)	6.5 (5.8-7.2)	8.5 (8.1-8.8)
4	32.2 (30.0-33.0)	29.6 (28.0-31.0)	8.9 (8.0-9.9)	10.6 (9.9-11.4)
6	28.2 (26.0-31.0)	30.2 (29.0-32.0)	10.5 (9.9-11.2)	9.5 (8.7-10.2)
8	24.8 (24.0-26.0)	30.6 (27.4-35.0)	8.7 (6.6-11.2)	10.1 (8.7-10.8)
10	26.2 (21.0-29.0)	25.8 (23.7-28.5)	9.9 (8.7-10.6)	10.0 (9.4-10.8)
13	36.2 (34.0-40.0)	31.0 (28.0-33.0)	10.1 (9.9-10.5)	10.1 (9.3-10.8)
16	28.0 (25.8-30.0)	26.0 (24.0-29.0)	9.2 (7.7-11.1)	9.0 (7.8-11.3)
19	27.4 (24.0-31.0)	30.5 (27.9-33.6)	9.1 (8.3-9.7)	9.4 (9.1-9.8)
22	29.1 (26.6-30.0)	30.0 (28.5-31.6)	9.4 (8.9-9.7)	8.7 (7.6-9.2)

Results are expressed as the mean values ( $\mu\text{moles}$  serotonin metabolized per gram in one hour) obtained from tissues of five animals. Figures in parentheses indicate the ranges of MAO activity.

for the rest of the animal's life span. This communication presents further information about the properties of MAO in the rat heart and its comparison with other tissues and species of animals.

Novick<sup>1</sup> first observed the relationship between the weight of the rat and cardiac MAO activity. There exists, however, a difference in the growth rate between the male and female rat, and this might affect the levels of cardiac MAO. A study was therefore made to determine the possible sex difference of MAO in the heart, liver and brain of the rat. Sprague-Dawley rats from ages 2 weeks to 22 weeks were employed in this study. MAO activity was measured by determining the rate of breakdown of 5-hydroxytryptamine (5HT) by tissue homogenates or mitochondria. The 5HT was assayed employing the nitroso-naphthol reaction as described by Udenfriend *et al.*<sup>2</sup>.

Table 1 demonstrates the MAO activity of the liver and brain of male and female rats during ages 2-22 weeks. Maximum MAO activity of both organs was evident by 6 weeks. Some degree of sex difference appeared to be present in liver MAO activity during the first 8 weeks of development, but its significance is questionable because of the variation from week to week. The heart exhibits a completely different picture in that at 2 weeks essentially no activity is present, but thereafter MAO progressively increases during the following 16-20 weeks (Fig. 1a). A plateauing appears at about the twentieth to twenty-fourth week in the male. At this time the MAO activity is equal to or exceeds that of the liver. The female exhibits a similar age-dependent relationship of cardiac MAO activity, but within 4-8 weeks shows a slower rate of increase and maintains a lower activity throughout the experimental period than that of the male.

If the cardiac MAO activities of the male and female rats are plotted against their weights as in Fig. 1b, one finds a greater degree of linearity than when related against age. Male rat heart MAO activity progressively increases up to 500-550 g while in the female the line stops at approximately the 250-300 g level, because further weight gain does not occur with increasing ages up to 30 weeks. It would appear that on a weight basis there is no difference between the male and female rat heart MAO, but on the basis of age there is a considerable difference.

The fact that the rat heart exhibits this progressively increasing MAO activity with age while the brain and liver does not led us to determine whether other organs and tissues behave in this manner. Assays of the intestines, kidney, spleen, aorta and skeletal muscle for MAO activity from rats of varying ages indicated that these structures acted more like the brain and the liver in that the maximum activity was already present in male rats weighing 100-150 g (8-12 weeks). This would lead us to believe that the rat heart was specific in this property. Further investigations have also disclosed that the age and weight dependent increase of cardiac MAO occurred not only in the heart, but also that MAO was the only enzyme that showed this relationship. Succinic dehydrogenase and cytochrome oxidase, both mitochondrial enzymes and abundant in heart tissue, did not

follow the age dependent relationship of MAO. Aldehyde dehydrogenase, a soluble fraction enzyme which is responsible for the second step of the MAO system (that of converting the aldehyde formed from the initial deamination of a substrate amine to the corresponding carboxylic acid), also did not follow the MAO activity curve with increasing age. Finally, determination of total protein content (according to the method of Lowry *et al.*<sup>3</sup>) of heart mitochondria from rats of varying ages showed no significant difference, again failing to follow the increase in cardiac MAO activity of the male rat.

Fig. 1. *a*, Graph representing the development of monoamine oxidase in male and female rat heart during ages 2–24 weeks. Each point represents the mean values from four to five animals. *b*, Relationship between cardiac monoamine oxidase activity and weight gain in male (black circles) and female (open circles) rats. Each point represents data from individual animals.

The MAO activity of hearts of several species of animals has also been examined at different age and weight levels, and it appears that of those animals investigated (mouse, guinea-pig, rat, rabbit and cat) the rat is the only species possessing this peculiar quality. This was also demonstrated histochemically by Studer<sup>4</sup>.

These experiments were carried out to establish and extend the observations of Novick. The results emphasize the presence of a sexual dimorphism in rats to the increase of MAO activity with age and it appears to be related to the rate of growth of the animals. The process of MAO increase as described herein is also specific for the heart and is species specific for the rat. Other enzymes in the rat heart do not follow the same relationship as MAO. Gey *et al.*<sup>5</sup> also noted that other enzymes involved in the metabolism of catecholamines, such as catechol-O-methyl transferase and dihydroxyphenyl-alanine-ketoglutarate transaminase, did not change with age.

The importance of changes in MAO activity of rat heart with age and sex differences is obvious in pharmacological studies which employ sympathomimetic amines which are substrates of MAO.

This study was supported by the US National Institute of Mental Health. I thank Mrs M. Carino for technical assistance.

## Tryptophan Residue in Aspergillopeptidase A

AMINO-ACID analysis has shown that the acid proteinase of *Aspergillus saitoi* (aspergillopeptidase A, EC, 3.4.4.17) contains one tryptophan and about twenty tyrosine residues in a molecule (average molecular weight, 34,550) (refs. 1–4). In this communication we describe the effect of chemical modification of aspergillopeptidase A and discuss the role of the single tryptophan residue in the molecule.

Aspergillopeptidase A, purified as before<sup>1</sup>, was removed on 'Sephadex G-100' at pH 4.0 to separate minor autodigestive products, and then lyophilized. Proteinase was estimated and amino-acid was determined, also as before<sup>1,2</sup>. Tryptophan was determined by the *p*-dimethylaminobenzaldehyde method<sup>3</sup>.

The concentration of aspergillopeptidase A is inversely proportional to the amount of *N*-bromosuccinimide<sup>4</sup> added at pH 4.1, and the enzyme is completely destroyed if about 40 moles of the compound is present for each molecule of enzyme at 0° C for 20 min. When the oxidized enzyme was fractionated with 'Sephadex G-100' the tryptophan, tyrosine and histidine residues were modified, but the other residues remained almost unchanged within the limit of experimental error (Table 1).

Aspergillopeptidase A was inactivated by photo-oxidation in the absence of sensitizers at pH 5.5. The enzyme solution was placed 20 cm from the centre of a Toshiba 'SHL-100' ultra-violet mercury lamp<sup>7</sup> at 11° C for 20 h. Amino-acid analysis of the modified and fractionated enzyme showed that only tryptophan and tyrosine residues had changed, even when inactivation had reached 60 per cent (Table 1).

Table 1. AMINO-ACID MODIFICATION WITH *N*-BROMOSUCCINIMIDE OR PHOTO-OXIDATION

Experimental condition	Amino-acid residues/molecule of aspergillopeptidase A				Activity presented (per cent)
	Histidine	Lysine	Tyrosine	Tryptophan	
Native	2.5	10.7	17.7	1.0	100
Oxidation with <i>N</i> -bromosuccinimide	1.8	10.0	7.4	0.4	14
Native	2.6	11.4	17.8	1.0	100
Photo-oxidation	2.5	10.7	15.6	0.4	40

Acetylation of the proteinase was performed at 0° C by adding excess of 100 molar *N*-acetylhydrazole<sup>10,11</sup> to a solution of  $2 \times 10^{-5}$  molar aspergillopeptidase A in 0.033 molar phosphate buffer, pH 7.0, containing 2 molar sodium chloride. The number of tyrosine residues acetylated in the modified enzyme molecule was 3.9 moles, calculated using a molar extinction coefficient of 1,160 at 278 mμ<sup>10</sup>. This value was obtained even when inactivation had reached 90 per cent of the control. We assume that the loss of the proteolytic activity is attributed to the modification of tyrosine residues.

A 50 molar excess of 2-hydroxy-5-nitrobenzylbromide<sup>8,9</sup> dissolved in 0.5 ml. of methyl alcohol was stirred with 4.5 ml. of native or denatured with 7 molar urea aspergillopeptidase A solution at 0°–2° C in acetate buffer, pH 4.1. After 75 min a sample of the treated enzyme solutions was passed through a column of 'Sephadex G-25' (1.8 cm × 72 cm) in 0.01 molar ammonium formate buffer, pH 4.1, to remove the uncombined 2-hydroxy-5-nitrobenzylbromide. The eluted solutions were dialysed and lyophilized. The number of tryptophan residues reacting with the 2-hydroxy-5-nitrobenzylbromide was calculated using a molar extinction coefficient of 18,900 (ref. 8) at 412 mμ in 0.1 normal potassium hydroxide. In the absence of urea, there was no reaction and the treatment had no

effect on the enzyme activity. On the contrary, calculation of the molar ratio of 2-hydroxy-5-nitrobenzylbromide to aspergillopeptidase A modified with 7 molar urea gave a value of 1.2. These findings agree with the previous conclusion that the single tryptophan residue is buried or strongly bound in the hydrophobic regions<sup>4</sup>. It therefore seems that the single tryptophan residue in aspergillopeptidase A is not at the active site of the enzyme, and that it has the function of stabilizing the conformation of the enzyme molecule.

### Kinetics of Acetylsalicylic Acid Disposition in Man

ALTHOUGH acetylsalicylic acid (ASA) has been in extensive clinical use since 1900, there is surprisingly little known with accuracy about the kinetics of absorption, metabolism, distribution and excretion of this drug in man and animals. Also, much of the present information has been indirectly estimated from the studies of the metabolite salicylic acid (SA). This has been a result of the lack of specific and sensitive methods for the determination of ASA in biological fluids. Further, while ASA has been shown to be present in the blood after an oral dose<sup>1-7</sup>, only the data of Leonards<sup>8</sup> allow an assessment of the elimination half-life of ASA in man (17 min). The latter data were obtained utilizing a method which relies on measuring ASA as the difference between free and total salicylate, however. We therefore decided to investigate in more detail the pharmacokinetics of ASA in man.

The study was conducted in four male subjects who each received an intravenous dose of ASA (650 mg) as the *N*-methylglucamine salt. Plasma levels of ASA were measured specifically using a gas-liquid chromatographic method and free SA was determined spectrophotofluorometrically.

The results obtained showed that the plasma concentration time curve of ASA can be described by a biexponential equation (see Fig. 1), with a very rapid half-life for both exponents (Table 1). The elimination half-life of ASA is 13–19.5 min, and therefore nearly all the ASA is eliminated from the body within 2 h of an intravenous dose. Also, with one subject who received various intravenous doses of ASA, there was a direct proportionality between the area under the ASA curve and dose, while the elimination half-life remained constant.

Oral administration of the same dose of ASA (650 mg), in solution, to these subjects resulted in a peak ASA plasma level occurring 15–25 min after the dose, indicating that the absorption is predominantly from the stomach. In some cases the half-life of the descending part of the ASA curve was longer than that obtained with the intravenous dose (Table 1). This, we think, is because absorption of ASA still occurs during the decline of the ASA plasma levels.

Table 1. TABLE SHOWING THE HALF-LIVES AND THE AREA UNDER THE ACETYSALICYLIC ACID CONCENTRATION TIME CURVES AFTER INTRAVENOUS AND ORAL ADMINISTRATION OF 650 MG ACETYSALICYLIC ACID

Subject	Route	Half-life (min)		Area ( $\mu\text{g/ml. min}$ )	Ratio of areas $\times 100$
		$\alpha^*$	$\beta^*$		
A	Intravenously	2.7	14.5	948	72.5
	Oral		15.0	687	
B	Intravenously	2.2	14.0	904	74.4
	Oral		17.0	673	
C	Intravenously	4.0	19.5	923	71.3
	Oral		19.5	658	
D	Intravenously	3.0	14.0	956	64.8
	Oral		18.0	620	

\*  $\alpha$  and  $\beta$  are the half-lives of the first and second exponent of the acetylsalicylic acid.

Without exception, however, the area under the ASA concentration time curve was lower (65–74 per cent) than that obtained after the intravenous dose (Table 1). In contrast, the SA plasma level after 1 h (when most of the ASA had been converted to SA) was the same after an oral or intravenous dose of ASA (Fig. 1). The latter finding shows that while ASA is totally available after an oral dose, as measured by SA plasma levels, only a part of the intact drug reaches the tissues and circulating fluids. Thus during the absorption of ASA, appreciable hydrolysis to SA must occur either in the gastrointestinal fluids, across the gut wall or during the first passage of this drug through the liver. It may be recalled that after an oral dose, all the drug passes through the liver via the hepatic portal vein; however, after an intravenous dose, the drug-containing blood goes to the heart and only 30 per cent of the cardiac output reaches the liver.

The influence of the gastrointestinal fluids on the hydrolysis of ASA is probably very small, as we showed that the drug was essentially stable in gastric and duodenal juices. On the other hand, a preliminary experiment in a dog indicated that the liver clearance of ASA is important. Thus, when ASA was infused into the dog via the jugular vein, hepatic portal vein, and given orally, the relative areas under the ASA curves were 100, 60 and 40 per cent, respectively. This result also suggests that esterases may be present in the gut wall. In addition, these data place some doubt on the use of the SA levels to assess the availability and absorption rate of ASA.

Fig. 1. Acetylsalicylic acid and salicylic acid plasma levels after intravenous and oral administration of 650 mg acetylsalicylic acid. Subject C. Intravenous study: ●—● acetylsalicylic acid; ▲—▲ salicylic acid. Oral study: ○—○ acetylsalicylic acid; △—△ salicylic acid.

Evidence to date shows that ASA is a more potent analgesic agent than SA (refs. 8 and 9) and thus it is important to have a knowledge of those factors that influence the availability of ASA, the route of administration being one. The formulation of the oral dosage form may be another factor.

We thank the Wellcome Foundation for support.

### Ribonucleases of Chronic Granulocytic Leukaemia Leucocytes

It has already been found that the ribonuclease activities of serum and urine of patients with chronic granulocytic leukaemia show characteristic variations related to this disease<sup>1</sup>. The behaviour of this enzyme in leukaemic leucocytes, however, has not been thoroughly studied. Recently, Ressler *et al.*<sup>2</sup> have demonstrated the presence of two electrophoretically separable ribonuclease fractions in leukaemic leucocytes. The present work is connected with the isolation and preliminary characterization of ribonucleases from chronic granulocytic leukaemia leucocytes. Some data concerning purification procedure have been presented earlier<sup>3</sup>.

A leucocytic mass containing about 75 per cent of mature granulocytes was used as the starting material for the isolation procedure. This mass (100 ml. in volume) was homogenized with 10 volumes of water and centrifuged for 10 min at 3,000*g*; from the supernatant inactive protein was precipitated by addition of solid sodium chloride to a concentration of 6 per cent (w/v). The precipitate was separated by centrifugation and rejected, and the supernatant was dialysed and applied to a column of 'CM-Sephadex C-50'.

The eluted material contained two overlapping ribonuclease peaks, as demonstrated by spectrophotometric determination of ribonuclease activity<sup>4</sup> in collected fractions. The active fractions corresponding to the individual peaks were pooled, lyophilized, and rechromatographed on 'Sephadex G-75' column. As a result, three active peaks, designated A, B and C, were obtained.

Repeated chromatography of the three peaks separately, and of pooled fractions corresponding to all three peaks, on 'CM Sephadex C-50' and 'Sephadex G-75', resulted in no increase in the number of peaks obtained. It was concluded from these experiments that the three ribonuclease fractions A, B and C are present in this material.

Table 1. SUMMARY OF ISOLATION PROCEDURE OF RIBONUCLEASES FROM LEUKAEMIC LEUCOCYTES

	Total activity (μg)	Purification ratio	Recovery (per cent)
Crude homogenate	7,500	1	100
Extract 6 per cent NaCl	7,300	1.7	97
First 'CM Sephadex' chromatography			
Ribonuclease I	2,040	26	27
Ribonuclease II	3,060	35	40
First 'Sephadex G-75' chromatography			
Ribonuclease A	820	45	11
*Ribonuclease B	1,750	94	23
*Ribonuclease C	1,520	109	20
Second 'CM Sephadex' chromatography			
*Ribonuclease A	464	56	6
*Ribonuclease B	1,115	180	15
*Ribonuclease C	975	207	13
Second 'Sephadex G-75' chromatography			
*Ribonuclease A	213	50	3
*Ribonuclease B	900	221	12
*Ribonuclease C	512	214	7

\* Only from peak fractions.

It was found that none of the three fractions showed any activity towards *bis-p*-nitrophenylphosphate nor do they depolymerize DNA. No effect was observed with lithium, sodium and potassium ions. Copper, zinc and manganese ions, however, produce some decrease in activity.

Ribonuclease present in fraction A shows an apparent molecular weight of about 24,000, as determined with a 'Sephadex G-75' column. It has an optimum pH of 5.8 and, in contrast to bovine pancreatic ribonuclease, is clearly unstable at a temperature of 95°C and a pH of 2.5.

Ribonucleases from fractions B and C (with molecular weights of 19,000 and 15,500 respectively) are both more

Fig. 1. Chromatography of proteins from 6 per cent sodium chloride extract on 'CM Sephadex C-50' column (2.2 × 25 cm), equilibrated with 0.05 molar acetate buffer pH 5.6. Gradient elution was performed by increasing the acetate concentration to 1 molar and increasing the pH to 7.8. Hatched area, ribonuclease activity.

Fig. 2. Elution of RNases from human leukaemic leucocytes on 'Sephadex G-75' (3.5 × 65 cm) column. The arrows show elution from this same column of γ globulin (a), pepsin (b), and bovine pancreatic RNase (c).

thermostable than fraction *A* of the enzyme, but still less so than bovine pancreatic RNase. The optimum pH is 6.8 for fraction *B* and 7.2 for fraction *C*.

Separation of the products released from yeast RNA by the action of isolated ribonuclease fractions revealed that RNase *A* differs markedly from RNases *B* and *C*, which are more or less similar. RNase *A* produced only a few products of low electrophoretic and chromatographic mobility, whereas RNases *B* and *C* formed one relatively immobile core with a number of smaller products showing much higher mobility.

The results obtained demonstrated the existence of at least two leucocytic ribonuclease fractions, one acidic and thermolabile, and the second neutral and thermostable.

### Metabolism of Orally Administered Dextran and 'Sephadex' Derivatives in the Rat

DEAE 'Sephadex A-25' has oral hypocholesterolaemic activity in cockerels and dogs<sup>1</sup>. This material is thought to interrupt the enterohepatic circulation of bile acids by binding them in the intestinal lumen and enhancing their excretion in the faeces. DEAE 'Sephadex A-25' is a cross-linked tertiary amine derivative of dextran with an average molecular weight of 25,000 and is insoluble in water and salt solutions. As such it would not be expected to be absorbed intact from the gastrointestinal tract. The possibility that the polymer might be hydrolysed by intestinal enzymes and the hydrolysis products absorbed has not, however, heretofore been investigated.

Chemical methods are not readily available for detecting hydrolysis products of DEAE 'Sephadex', or of the intact polymer, in biological fluids or tissues. It has, however, been shown that oral administration of dextran leads to an early increase in blood sugar and liver glycogen in rats and man<sup>2</sup>. This is presumably the result of hydrolysis of dextran to glucose by intestinal enzymes<sup>3</sup>. To determine whether or not DEAE 'Sephadex' is metabolized in a similar manner, the hyperglycaemic and glycogenic effects of dextran and DEAE 'Sephadex', together with other dextran derivatives, were compared in fasting rats. The extent of hydrolysis of these materials by homogenates of small intestinal mucosa was also determined.

Male Sprague-Dawley rats, 243–325 g, which had been maintained on a semisynthetic diet, were fasted for 24 h. Animals then received by stomach tube 500 mg of the material to be tested, dissolved or suspended in 5 ml. of distilled water. 4 h later the animals were anaesthetized with an intraperitoneal injection of 'Cyclopal' [5-allyl-5(2-cyclopenten-1-yl)barbituric acid] and blood samples were taken from the abdominal aorta in heparinized syringes for analysis of glucose. Livers were excised, rinsed in saline, blotted dry and weighed. Samples of about 500 mg were dropped immediately into glass centrifuge tubes containing 1 ml. of 30 per cent potassium hydroxide. The tubes were heated in boiling water for 30 min. 3 ml. of distilled water and 5.5 ml. of 95 per cent ethanol were added and the tubes were placed

Table 1. HYPERGLYCAEMIC AND GLYCOGENIC EFFECTS OF DEXTRAN AND 'SEPHADEX' DERIVATIVES IN FASTED RATS

Material administered	Blood glucose (mg/100 ml.)	Liver glycogen (mg/g)
Distilled water	85 ± 2.7	1.0 ± 0.33
Glucose	104 ± 2.7	6.8 ± 0.61
Dextran 60-C*	101 ± 1.8	6.2 ± 1.47
DEAE dextran†	91 ± 6.3	5.6 ± 1.46
'Sephadex G-25'	87 ± 3.6	4.7 ± 1.97
DEAE 'Sephadex A-25'	81 ± 4.6	0.6 ± 0.37

Glucose was determined in whole blood by the potassium ferrioxalate-potassium ferrocyanide method of Hoffman<sup>4</sup> adapted to the 'Technicon' auto-analyser. Although this method is sensitive to other blood reducing substances, normal concentrations of these substances are relatively insignificant compared with glucose levels. The results represent means ± standard error of the mean, ten animals in each group.

Table 2. HYDROLYSIS OF DEXTRAN AND 'SEPHADEX' DERIVATIVES BY HOMOGENATES OF SMALL INTESTINAL MUCOSA

Substrate	Hydrolytic activity (μmoles maltose equiv./60 min)
Dextran 60-C	8.66
DEAE dextran	2.44
'Sephadex G-25'	0.14
DEAE 'Sephadex A-25'	0.06

Twenty mg of substrate dissolved or suspended in 1 ml. of 0.1 molar maleate buffer (pH 6.0) and 1 ml. of homogenate were incubated for 60 min at 37° C. Hydrolytic activities were corrected for reducing substances present in the homogenate. The results are the means of duplicate samples.

again in boiling water to precipitate the glycogen. The tubes were cooled in tap water for 10 min and centrifuged. Supernatant fluid was decanted and the glycogen was dissolved in distilled water. Glycogen was determined by the anthrone method of Seifter *et al.*<sup>4</sup> using a glucose standard.

Intestinal mucosa homogenates were prepared from rats fasted for 24 h. The animals were killed by a blow on the head and the proximal two-thirds of the small intestine was excised, rinsed in cold saline and slit longitudinally on an iced glass plate. Mucosa was scraped off with the edge of a microscope slide and homogenized in 4 ml. of cold saline per g tissue in a 'Lourdes' tissue homogenizer at full speed for 1 min. The homogenate was centrifuged for 10 min at 2,000g at 0° C. The supernatant fraction was used to assay for hydrolytic activity according to the procedures of Dahlqvist<sup>3,5</sup> for determining amylase and dextranase activity. Hydrolytic activity is expressed as the increase in reducing power equivalent to 1 μmole of maltose for 60 min at 37° C.

Blood sugar concentration in rats dosed with glucose and dextran was significantly increased after 4 h (Table 1). In animals dosed with DEAE dextran, 'Sephadex G-25', or DEAE 'Sephadex A-25' blood sugar was not significantly different from controls given distilled water. Liver glycogen increased between five and seven times in rats given glucose, dextran, DEAE dextran, or 'Sephadex G-25'. DEAE 'Sephadex A-25', on the other hand, produced no noticeable change in liver glycogen. An apparent discrepancy exists because DEAE dextran and 'Sephadex G-25' were markedly glycogenic but did not increase blood sugar. On the other hand, in a previous study<sup>2</sup> maximum elevation of blood sugar occurred in rats 0.5 to 2 h after dosing with 450 mg of dextran, and blood sugar concentration had returned to control values after 4 h. It is therefore probable that blood sugar was elevated by DEAE dextran and 'Sephadex G-25' also, but that this was not detected when samples were taken after 4 h.

The results in Table 2 show that DEAE dextran is extensively hydrolysed *in vitro* by an enzyme preparation previously shown to hydrolyse dextran itself<sup>3</sup>. 'Sephadex G-25', an insoluble cross-linked dextran, is also hydrolysed, although to a much smaller extent, while DEAE 'Sephadex A-25' is not affected significantly.

These experiments indicate that DEAE 'Sephadex A-25' is resistant to degradation in the intestinal lumen. It seems unlikely therefore that any appreciable amount

of this material could be absorbed after oral administration.

I thank Mrs F. L. Schmidt for performing the blood glucose analyses and J. C. Schneider, jun., for his expert technical assistance.

### Free Amino-acids in Human Sweat from Different Parts of the Body

THE presence of free amino-acids in human sweat has been known since 1910 when Embden and Tachau<sup>1</sup> isolated serine from this secretion. In 1946, Hier, Cornbleet and Bergeim<sup>2</sup> identified arginine, histidine, isoleucine, leucine, lysine, phenylalanine, threonine, tryptophane, tyrosine and valine in human sweat; they were also able to demonstrate that the amount of amino-acids secreted in sweat is independent of the diet and of variations in amino-acid levels in the blood; Rothman and Sullivan<sup>3</sup> found two additional amino-acids to be present in sweat, ornithine and citrulline. This observation, together with the high urea level of sweat<sup>4</sup>, led to the hypothesis that urea is formed in the sweat glands<sup>2,3</sup>. Hamilton<sup>5</sup>, and Oró and Skewes<sup>6</sup>, using ultra-micro methods, found the relative concentrations of amino-acids on the surface of the fingers of ten subjects to be essentially constant. Other authors<sup>7</sup> who sampled sweat from the whole body surface, rather than from a single area, reported greater individual differences.

For the study of regional differences, sweat was collected from the hands and (or) backs of forty-two children and adults of both sexes, aged from 2 months to 62 yr. Among them twenty-eight individuals each furnished a sample from both sites.

For the collection of sweat, the following procedure was adopted: the skin of the hands and back was washed with alcohol, ether and warm distilled water and plastic bags were fixed with adhesive tape to the wrists (enclosing the hands) and backs (in the interscapular region between the seventh cervical and the twelfth thoracic vertebra). Strips of weighed filter paper were introduced into the bags and removed after 5 h; 0.5–2 g of sweat was normally obtained. The amino-acids were eluted from the paper with distilled water and the eluate was evaporated to dryness. The dry material was dissolved in a measured volume of buffer solution and samples containing approximately 20  $\mu$ moles of ninhydrin positive substances were used for amino-

acid analysis by the method of Spackman, Stein and Moore<sup>8</sup>. With the method of sweat collection used, it is difficult to eliminate completely evaporation of water during the sampling period. The results were therefore expressed as relative concentrations; threonine, which was found in almost equal amounts in sweat from both sites, was used as the reference substance (Fig. 1 and Table 1).

Very significant differences between sweat from hands and backs were found for ornithine and citrulline, the relative concentration of ornithine being approximately eight times higher in sweat from the hands than in sweat from the back and that of citrulline approximately five times higher in sweat from the back than in sweat from hands. Arginine and urea, like citrulline, were significantly higher in sweat from backs than in sweat from hands. Of the other seventeen amino-acids, the threonine quotients of valine, isoleucine, leucine, tyrosine and proline were significantly higher in sweat from hands than in sweat from backs, but these differences were small compared with the differences mentioned here in ornithine citrulline, arginine and urea. No differences were found for threonine, lysine, histidine, tryptophane, aspartic

Fig. 1. Threonine quotient ( $\mu$ moles amino-acid or urea/ $\mu$ moles threonine) for twenty amino-acids and urea in sweat from children and adults of series I (Table 1). Black columns: sweat from hands; white columns: sweat from backs. The height of the columns indicates the mean values. One standard deviation (S.D.) is graphically represented for most of the amino-acids; where this is not the case, S.D. was  $< 0.02$ . The relatively high S.D. for urea might partially be caused by the small extinction coefficient of the ninhydrin coloration<sup>8</sup>.

acid, serine-glutamine-asparagine (no separate determinations), glutamic acid, glycine, alanine, cystine, methionine and phenylalanine. The means, ranges and standard deviations of values for ornithine, citrulline, arginine and urea are given in Table 1.

For the study of amino-acid patterns in sweat from patients with anomalies of amino-acid metabolism, sweat was collected from two adult male individuals with cystinuria, one girl aged 4 with cystine storage disease and Fanconi syndrome, one boy aged 1 with the non-ketotic type of hyperglycinaemia, one boy aged 2 with phenylketonuria and one boy aged 10 months with oculocerebro-renal syndrome (Lowe syndrome). When the values for the amino-acids in the sweat of these patients were compared with those from healthy controls, no significant differences in the relative concentrations were observed, but all showed the characteristic differences between sweat from hands and backs. These values were therefore included in the study of regional differences.

Table 1. THREONINE QUOTIENTS ( $\mu$ MOLES AMINO-ACID OR UREA/ $\mu$ MOLES THREONINE) FOR ORNITHINE, CITRULLINE, ARGININE AND UREA IN SWEAT FROM CHILDREN AND ADULTS

			Threonine quotient			UREA
			ORN THR	CIT THR	ARG THR	THR
Hand	Series I n = 12	Mean	2.26 ± 0.26	0.26 ± 0.03	0.09 ± 0.02	3.59 ± 0.54
		Range	1.54 - 4.79	0.13 - 0.44	0.03 - 0.29	1.82 - 7.07
	Series II n = 20	Mean	1.74 ± 0.12	0.19 ± 0.03	0.13 ± 0.02	—
		Range	1.10 - 2.81	0.07 - 0.55	0.01 - 0.27	—
Back	Series I n = 18	Mean	0.26 ± 0.07	1.48 ± 0.08	0.31 ± 0.04	13.08 ± 2.60
		Range	0.05 - 0.91	0.82 - 2.19	0.03 - 0.51	1.51 - 49.90
	Series II n = 20	Mean	0.09 ± 0.01	1.72 ± 0.12	0.27 ± 0.04	—
		Range	0.06 - 0.12	0.88 - 2.58	0.01 - 0.57	—
P = Level of significance		Series I	< 0.001	< 0.001	< 0.002	0.01 - 0.002
		Series II	< 0.001	< 0.001	< 0.050	—

The values of series I are included in Fig. 1. The thirty samples were taken from twenty-two individuals, whereby eight persons furnished samples of both sites. Confirming results from a later and independent set of determinations are represented in series II, where each individual provided a sample from both sites. The only difference between the two series concerns the P-values for ARG/THR.

The values for P were obtained with the X-test<sup>11</sup>. n = Number of sweat samples.

From the data presented, the following conclusions can be drawn. The relative concentrations of free amino-acids in human sweat from a specific area show only minor individual variations. This finding is in agreement with the data of Oró and Skewes<sup>6</sup>, who found little individual variation in amino-acid patterns from fingers. Some authors<sup>7</sup> have reported higher individual variations for ornithine, citrulline, arginine and asparagine; such variations may be obtained when the two types of sweat are mixed (for example, in thermal sweat from the whole body surface).

Notable regional differences occur in the relative concentrations of the amino-acids involved in the urea cycle and in those of urea: ornithine is high in sweat from the hands (mainly palmar sweat) but low in sweat from the back; in contrast, the relative concentrations of citrulline, arginine and urea are higher in sweat from the back than in sweat from hands. With the present state of knowledge it is difficult to suggest a possible mechanism for these differences, because not enough is known about the metabolism of the eccrine sweat glands and about the secretion mechanism of amino-acids of sweat. The observation that palmar and back-sweat show marked differences in urea cycle amino-acids suggests, however, that the eccrine sweat glands in the two locations, although morphologically identical<sup>8</sup>, have different properties with respect to the metabolism of urea and the amino-acids involved in the urea cycle. It is most unlikely that the differences are artefacts (results of bacterial action, admixture of apocrine sweat or secretion from sebaceous glands, different degree of keratinization) because the differences occurred with great constancy in all subjects regardless of age, sex, degree of keratinization

or presence of hairs. Furthermore, such artefacts would probably also affect other amino-acids.

In some anomalies of amino-acid metabolism (cystinuria, cystine storage disease, hyperglycinaemia, phenylketonuria, Lowe syndrome) the pattern of sweat amino-acids appears to remain unchanged, despite marked alterations in plasma and/or urine amino-acid levels. This finding is in agreement with the observation of Hier, Cornbleet and Bergeim<sup>2</sup> that levels of the amino-acids of sweat are independent of changes in plasma amino-acids and that amino-acids do not appear in the sweat merely as a result of filtration from the blood plasma. Because, however, anomalies of amino-acid metabolism and amino-acid transport may affect the sweat glands as well as other organs, it is possible that such alterations will be found when more "inborn errors" of amino-acid metabolism are investigated. Coltman, Rowe and Atwell<sup>10</sup> have, in fact, recently reported a generalized increase of amino-acid concentrations in sweat in patients with Wilson's disease.

We thank Professor P. S. Chen for discussion.

## Stabilization of Enzyme Activity by an Organic Solvent

BIOCHEMICAL work with unstable enzymes is often handicapped by the loss of their enzyme activity during preparation and storage, and the instability of the enzymes makes their further purification and study difficult. A number of enzymes can be stabilized with the use of reducing agents, chelating compounds, competitive inhibitors, co-enzymes, and substrates and their analogues. Recently, Nozaki, Kagamiyama and Hayaishi<sup>1</sup> have found that metapyrocatechase from *Pseudomonas sp.*, which is very unstable, particularly in the presence of air, is stabilized by the presence of a low concentration of an organic solvent such as acetone or ethanol, and this observation led to its purification and crystallization. This has led us to investigate whether organic solvents have a stabilizing effect on a wide variety of enzymes. In this communication we report the effects of acetone and ethanol in stabilizing benzylalcohol dehydrogenase from *Pseudomonas sp.*, homogentisicase from bovine liver, and alcohol dehydrogenase from yeast.

Benzylalcohol dehydrogenase, which catalyses the oxidation-reduction of benzylalcohol and benzaldehyde with stoichiometric amounts of nicotinamide adenine dinucleotide and reduced nicotinamide adenine dinucleotide,

respectively, was observed to be markedly unstable<sup>2</sup>. The dehydrogenase had a half-life of a few hours in 0.05 molar phosphate buffer, pH 7.5 at 5° C, and reducing or chelating agents had no significant retarding effect on the loss of activity. An organic solvent such as acetone or ethanol, however, was found to cause significant and often complete stabilization of the dehydrogenase. Experiments collected in Fig. 1A indicate that incubation at 5° C and pH 7.5 of the dehydrogenase caused rapid inactivation, but the presence of 10 per cent acetone was found to protect the dehydrogenase from inactivation almost completely. As shown in Fig. 1B, the protective effect of ethanol was similar to that observed in acetone. Similar protection was also observed in ammonium sulphate (Fig. 1C). A further point of interest is whether the inactivation is prevented by maintaining the dehydrogenase anaerobically. To this end incubation was carried out in an atmosphere of nitrogen with a Thunberg tube at 5° C and it was found that anaerobic conditions do not stabilize the dehydrogenase (Fig. 1C).

Yeast alcohol dehydrogenase is relatively unstable compared with liver alcohol dehydrogenase, although the former is quite stable in a crystalline suspension in ammonium sulphate or under conditions in which oxidation of -SH groups cannot occur. The dehydrogenase was markedly unstable at a low concentration of the protein

Fig. 1. A and B, Stability of benzylalcohol dehydrogenase in an organic solvent. Enzyme (46  $\mu\text{g}/\text{ml}$ ) was stored at 5° C in 0.05 molar phosphate buffer, pH 7.5, which contained different concentrations of acetone or ethanol. At the times indicated aliquots were transferred to the reaction mixture and assayed under standard conditions<sup>2</sup>. A, Acetone; B, ethanol;  $\blacksquare$ , 20 per cent;  $\bullet$ , 10 per cent;  $\square$ , 5 per cent;  $\triangle$ , 2 per cent;  $\circ$ , none. C, Stability of benzylalcohol dehydrogenase in ammonium sulphate and under anaerobic conditions. Enzyme (46  $\mu\text{g}/\text{ml}$ ) was stored at 5° C in 0.05 molar phosphate buffer, pH 7.5, which contained different concentrations of ammonium sulphate. Anaerobic experiments were carried out under nitrogen in a Thunberg tube.  $\bullet$ , 1 molar;  $\square$ , 0.5 molar;  $\circ$ , none;  $\times$ , nitrogen atmosphere.

Fig. 2. Stability of yeast alcohol dehydrogenase in acetone and in glutathione. The enzyme was dissolved in 0.05 molar phosphate buffer, pH 7.5, at the protein concentration of 22  $\mu\text{g}/\text{ml}$ , and was incubated with acetone at concentrations of 20 per cent ( $\blacksquare$ ) and 10 per cent ( $\bullet$ ), respectively. The control system was without acetone ( $\circ$ ). Likewise, the enzyme was incubated with 1 mmolar glutathione ( $\circ$ ). The incubation was carried out aerobically at 26° C. At the times indicated, aliquots were transferred to the reaction mixture and assayed as previously described by Racker<sup>4</sup>.

Fig. 3. Stability of homogentisicase in an organic solvent. The apo- and holoenzymes of homogentisicase were prepared as described previously<sup>3</sup>. Enzymes (106  $\mu\text{g}/\text{ml}$ ) were in 0.01 molar phosphate buffer, pH 7.0, which contained different concentrations of acetone and were incubated at 4° C in air. Anaerobic experiments were carried out under nitrogen in a Thunberg tube. At the times indicated, aliquots were transferred to the reaction mixture and assayed as described previously<sup>3</sup>. A, Holoenzyme; B, apoenzyme.  $\blacksquare$ , 20 per cent;  $\blacktriangle$ , 15 per cent;  $\bullet$ , 10 per cent;  $\circ$ , none;  $\times$ , nitrogen atmosphere.

in 0.05 molar phosphate buffer, pH 7.5 at 26° C, as shown in Fig. 2. When the dehydrogenase was incubated in the presence of 20 per cent acetone, the inactivation was considerably reduced. Likewise, in the presence of 1 mmolar glutathione the enzyme suffered no loss of activity, even after 20 h.

Bovine liver homogentisicase, which is generally known as dioxygenase and catalyses oxidative cleavage of the aromatic ring of homogentisic acid, was observed to be highly unstable, particularly in the presence of air. The presence of a low concentration of acetone protected the holoenzyme from inactivation by air<sup>3</sup> (Fig. 3A). Ethanol also retarded inactivation. The apoenzyme (which is completely inactive in the absence of ferrous iron) was found to be completely stable in the presence of 10 per cent acetone, even after 24 h storage in air. In contrast to the holoenzyme, no appreciable protective effect of the apoenzyme was observed under anaerobic conditions.

These phenomena of the apoenzyme were quite similar to those observed in the case of benzylalcohol dehydrogenase.

It appears that the inactivation in the case of benzylalcohol dehydrogenase or the apoenzyme of homogentisicase is not caused by the destruction of any oxy-labile groups in the enzyme protein, and that the stabilization of the enzyme activity by the organic solvent is probably caused by maintenance of the "native state" of the protein conformation. It is noteworthy that the organic solvent such as acetone or ethanol is effective for the stabilization of unstable enzymes, and can be used in practice without significant interference in chromatographic systems during the process of enzyme purification. The mechanism of the protection by the organic solvent will be better interpreted by further investigations on physico-chemical properties of the protein molecule in aqueous organic solvents.

This investigation was supported in part by a Tanabe amino-acid research grant. We thank Messrs F. Takayanagi, H. Yasuda and K. Suzuki of our laboratory for their help.

### Structural Basis for Phosphorylation of Adenosine Congeners

DURING the past few years the metabolism by mammalian cells of a number of natural and synthetic nucleosides structurally related to adenosine has been investigated in this<sup>1-5</sup> and other laboratories<sup>6-10</sup>. In our studies with Ehrlich ascites cells, we have tried to establish a correlation between the structural variations and the utilization by cells of these nucleosides and have observed the following salient features: (a) In order to be phosphorylated to the 5'-triphosphate level, the adenosine analogue must have a primary amino group at the C-6 position of the purine moiety. Compounds that belong in this category are 3'-deoxyadenosine<sup>2,6</sup>, 3'-amino-3'-deoxyadenosine<sup>4</sup> and 2-fluoroadenosine<sup>3</sup>. These three nucleosides were also found to be potent inhibitors of nucleic acid synthesis in Ehrlich ascites cells. Work in other laboratories has shown that 7-deazaadenosine<sup>7</sup>, xylosyladenine<sup>8</sup>, arabinosyladenine<sup>9</sup> and the bases 2-azaadenine and 2,6-diaminopurine<sup>10</sup> were also phosphorylated to 5'-triphosphate. 2,6-Diaminopurine is also metabolized to the triphosphate level by microbial cells<sup>11,12</sup>. Removal of the 6-amino group as in 3'-deoxynuclearine resulted in complete absence of phosphorylation by ascites cells<sup>4</sup>. (b) 6-Methylaminopurine ribonucleoside—an adenosine analogue with a 6-methylamino group—was metabolized to the monophosphate level only<sup>4</sup>. This was also found to be so for 6-methylaminopurine-2'-deoxyribonucleoside, 6-methylaminopurine-3'-deoxyribonucleoside and 6-methylaminopurine<sup>5</sup>. (c) Replacement of the 6-amino group by 3'-deoxyadeno-

sine with an ethylamino or dimethylamino group completely suppressed the capacity of the nucleoside for phosphorylation. This relationship was exemplified by 6-ethylaminopurine-3'-deoxyribonucleoside and 6-dimethylaminopurine-3'-deoxyribonucleoside<sup>4</sup>. Furthermore, 6-dimethylamino-3'-amino-3'-deoxyribonucleoside was also inactive, while its parent compound, as already mentioned, was readily phosphorylated. Nucleosides that were not phosphorylated had almost no effect on nucleic acid synthesis.

This work has been continued with several new synthetic adenosine analogues, and the structure-activity relationships and structural specificity for phosphorylation of these compounds are described and discussed in this communication.

2-Fluoro-3'-deoxyadenosine, 5'-5'-dimethyladenosine, 3'-deoxy-3-isoadenosine and tritiated 3'-C-methyladenosine<sup>13</sup> were supplied by Drs E. Walton and F. Holly. 2',3'-Dideoxyadenosine was prepared and supplied by Dr R. K. Robins<sup>14</sup>.

The procedures used to study the phosphorylation of adenosine analogues have already been described<sup>2-4</sup>. In brief, the perchloric acid-soluble portion of ascites cell incubated with the test nucleoside was fractionated by means of 'Dowex-1'-formate chromatography. The materials obtained were characterized by measurements of ultra-violet absorption, phosphate determination and by paper electrophoresis or chromatography. The methods used to determine deamination or cleavage of nucleosides have been described<sup>4</sup>.

A study of the metabolism of 3'-C-methyladenosine was especially interesting because this compound is the first derivative of adenosine with a branched-chain pentose. This nucleoside was not deaminated or cleaved by intact Ehrlich ascites cells. When tritiated 3'-C-methyladenosine was incubated with ascites cells for 3 h at 37° C and the substance soluble in hydrochlorous acid was fractionated by ion-exchange chromatography, a radioactive material which absorbed in the ultra-violet was eluted from the region corresponding to nucleotide triphosphate. This substance had an absorption spectrum similar to that of adenosine or 3'-C-methyladenosine ( $\lambda_{\max}$  258,  $\lambda_{\min}$  227, 250/260 = 0.79, 280/260 = 0.16) at pH 7 and contained 3.2  $\mu$ moles of phosphorus/ $\mu$ mole of adenosine. On paper electrophoresis at pH 3.5, the mobility of the substance was found to be comparable with that of ATP. These results, in addition to the observation that this analogue was not deaminated or cleaved, indicated that the radioactive

Fig. 1.

\* A possible exception to this rule was demonstrated by Gordon *et al.* (*J. Amer. Chem. Soc.*, **79**, 3256; 1957) when they showed that 9- $\beta$ -D-ribofuranosyl purine was phosphorylated in the adult rat.

\* This communication.

triphosphate obtained from the acid-soluble fraction was 3'-C-methyladenosine triphosphate. Similar experiments showed that the following new adenosine analogues were not phosphorylated at all: 2-fluoro-3'-deoxyadenosine, 5',5'-dimethyladenosine, 2',3'-dideoxyadenosine and 3'-deoxy-3-isoadenosine. The chromatographic patterns of the acid-soluble fractions from these experiments were similar to those in the control experiments<sup>4</sup>.

These results thus show that another adenosine analogue (3'-C-methyladenosine) with a 6-amino group was phosphorylated to the triphosphate level and it is also noteworthy that a methyl group on the 3'-position of the ribose moiety did not interfere with the utilization of the nucleoside. The results obtained with the other new adenosine analogues also substantiate the view<sup>4</sup> that although the 6-amino group is essential for phosphorylation, its mere presence does not necessarily ensure phosphorylation. The fact that 2-fluoro-3'-deoxyadenosine was inert while both 2-fluoroadenosine and 3'-deoxyadenosine were phosphorylated suggested that substitution of 3'-OH with 3'-H altered the property of the 2-fluoro-adenine moiety of the nucleoside. The inactivity of 2',3'-dideoxyadenosine indicated that at least one hydroxyl group is required at either the 2'- or 3'-position of the pentose moiety. Steric hindrance caused by the relatively bulky methyl groups at the site of phosphorylation and diminished reactivity of the tertiary hydroxyl group may explain the inactivity of 5',5'-dimethyladenosine. Transfer of the 3'-deoxyribosyl group from the N-9- to the N-3-position also hindered phosphorylation.

Thus adenosine can be made to undergo certain structural modifications and yet retain its capacity for conversion to the triphosphate. The structural alterations that are known to permit phosphorylation can be summarized as follows (Table 1 and Fig. 1).

- Position 2: Fluorine could replace hydrogen (2-fluoroadenosine)
- NH<sub>2</sub> could replace hydrogen (2,6-diaminopurine)
- Nitrogen could replace CH (2-azaadenine)
- Position 7: CH could replace nitrogen (7-deazaadenosine)
- Position 2': Either epimer (ribose or arabinose)
- Position 3': Either epimer (ribose or xylose)
- Hydrogen for hydroxyl (3'-deoxyadenosine)
- NH<sub>2</sub> for hydroxyl (3'-amino-3'-deoxyadenosine)
- Methyl for hydrogen (3'-C-methyladenosine)

Modifications of adenosine or 3'-deoxyadenosine that do not allow phosphorylation to triphosphate can be outlined as follows (although much of this work was done with 3'-deoxyadenosine analogues, it is assumed that the structure-activity relationship of these nucleosides can be extrapolated to adenosine because 3'-deoxyadenosine was phosphorylated nearly as well as adenosine).

- Position 6: NH<sub>2</sub> replaced by H, CH<sub>3</sub>NH, C<sub>2</sub>H<sub>5</sub>NH or (CH<sub>3</sub>)<sub>2</sub>N
- Position 1': Hydrogen replaced by CH<sub>2</sub>OH (psicofuranine, ref. 15).
- Position 5': 2H replaced by (CH<sub>3</sub>)<sub>2</sub>
- Positions 2 and 3': Simultaneous changes at C-2 (F for H) and 3' (H for OH) as in 2-fluoro-3'-deoxyadenosine.
- Positions 2' and 3': Simultaneous changes at 2' (H for OH) and 3' (H<sub>2</sub> for OH) as in 2',3'-dideoxyadenosine.
- Position 9: Transfer of 3'-deoxyribosyl group from N-9 to N-3.

### Reversal by Phosphate of Glucose Repression of Catalase Synthesis in *Saccharomyces cerevisiae*

It has long been known that glucose represses many inducible enzyme systems<sup>1</sup>. The mechanism responsible for this specific effect has elicited wide interest although none of the suggestions put forward has received unqualified acceptance. Neidhart and Magasanik<sup>2</sup> and Mandelstam<sup>3,4</sup> have concluded from their studies on  $\beta$ -galactosidase that any compound utilized by the organism as a source of energy and carbon can act as repressor and that it may not be glucose itself but a catabolite derived from it that is the active repressor. According to the "feedback hypothesis" of Neidhart and Magasanik<sup>5</sup> and Vogel<sup>6</sup>, the formation of each catabolic enzyme is controlled by the intracellular concentration of some particular metabolite which is an immediate or ultimate product of that enzyme and which is also produced from glucose at a rate faster

than its utilization for synthetic reactions in the cell. A possible site of glucose action is the release of the enzyme from the RNA template<sup>7</sup> or ribosome<sup>8</sup>.

In the course of our work on the induction of catalase, when anaerobically grown cultures of *Saccharomyces cerevisiae*<sup>9,10</sup> were aerated, we observed (Table 1) that glucose had a stimulatory effect at low concentrations but a repressive effect at concentrations higher than 56  $\mu$ moles/ml. Of the various catabolites of glucose which we tested, lactate and acetate showed a similar behaviour; however, succinate and citrate were highly inhibitory whereas pyruvate was stimulatory. Of the other sugars and related compounds tested, fructose, mannose and galactose gave a response qualitatively similar to that with glucose while sorbose and glycerol stimulated the induction with increasing concentrations. The repressive effect of glucose diminished as the sugar was used up so that by extending the time of aeration the induction could again be demonstrated.

Table 1. EFFECTS OF SUGARS AND GLUCOSE METABOLITES ON INDUCED SYNTHESIS OF CATALASE

Addition to aeration medium	$\mu$ moles/ml.		
	14	140	280
	Percentage of alteration in catalase activity		
Glucose	+15.0	-24.6	-42.9
Pyruvate	+10.9	+18.1	+20.8
Lactate	+3.0	-7.2	-21.5
Acetate	+12.3	+3.1	-62.2
Succinate	-5.1	-25.0	-100.0
Citrate	-20.6	-30.3	-100.0
Fructose	+3.7	-24.8	-34.0
Mannose	+9.4	-24.9	-42.3
Galactose	+19.2	+7.8	-15.5
Sorbose	+11.1	+31.6	+36.0
Glycerol	+9.4	+24.3	+29.2

Cells of *Saccharomyces cerevisiae*, grown anaerobically in glucose-peptone-yeast extract medium, were collected and washed. Quantities of about 200 mg dry weight were suspended in 10 ml. of the aeration medium ( $\text{KH}_2\text{PO}_4$ , 1.0 per cent;  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ , 0.01 per cent;  $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ , 0.01 per cent, pH 6.8) and aerated for 4 h. At the end of the period the cells were centrifuged, washed, treated with a few drops of chloroform and catalase activity was assayed as described previously<sup>9</sup>. The glucose catabolites tested were used at double the stated concentrations.

The inhibition by glucose of catalase induction may be a case of "catabolite repression". On the other hand, the possibility cannot be dismissed that glucose inhibits the respiratory enzymes with a consequent decrease of the *in situ* production of hydrogen peroxide which appears in the present case to be the inducer. In fact, it was observed that at higher concentrations glucose inhibited the respiration of the yeast cells, an observation analogous to the Crabtree effect observed with tumour cells<sup>11</sup>. In view of the report that the Crabtree effect is reversed by inorganic phosphate<sup>12</sup>, we studied its effect on the induction of catalase (Table 2).

Table 2. REVERSAL BY PHOSPHATE OF GLUCOSE REPRESSION OF CATALASE

Phosphate in aeration medium ( $\mu$ moles/ml.)	Catalase activity Kat f units in the presence of glucose in aeration medium ( $\mu$ moles/ml.)	
	14	280
73	718	396
146	723	670
219	727	730
292	734	840
365	740	915

We observed that an increase in the concentration of phosphate in the aeration medium did not appreciably affect the synthesis of catalase when glucose was present at a low concentration. The inhibition produced by high concentrations of glucose could, however, be overcome by increasing the concentrations of phosphate. The inhibition of respiration by glucose, on the other hand, was not reversed by increased concentrations of phosphate. It is interesting to recall in this context the observations of Mandelstam<sup>3,4</sup>, during his studies on the formation of  $\beta$ -galactosidase in *Escherichia coli*, that any carbon source metabolite will cause repression when the cells are starved of nitrogen, magnesium ions or some specific auxotrophic factor. The present observation demonstrates that

glucose inhibits the induction phenomenon by creating a deficiency of inorganic phosphate.

### Multinucleated Muscle Fibres: Induction of DNA Synthesis and Mitosis by Polyoma Virus Infection

In many cell types differentiation is closely associated with the end of DNA synthesis. The differentiation of muscle cells is a typical example. The formation of muscle fibres takes place by the successive fusion of mononucleated myoblasts into ribbon like cells, containing as many as several hundred nuclei. After fusion, the nuclei within the fibres do not synthesize DNA, do not undergo mitosis<sup>1-4</sup> and apparently are also restricted in RNA synthesis<sup>5,6</sup>.

The aim of the present work was to test whether the formation of multinucleated muscle fibres is associated with an irreversible block of DNA synthesis, or whether the nuclei within the fibres can be induced to resume DNA synthesis and undergo mitosis. Previously it was shown that the oncogenic viruses polyoma (PV) and SV40 can induce host DNA synthesis and cell division in contact inhibited cells and also induce DNA synthesis in X-irradiated cells<sup>7-11</sup>. It was thus decided to test whether an oncogenic virus can induce host DNA synthesis in rat multinucleated muscle cells. Cells of these species were selected because rat fibroblasts had previously been shown to undergo malignant transformation by PV in the absence of the synthesis of infectious virus particles. It was hoped that rat muscle cells would also not support PV multiplication and thus facilitate observation of host DNA synthesis and eliminate the complication of cell lysis.

Cells obtained by trypsinization of newborn rat thigh muscle cells were cultured as previously described<sup>4,6</sup>. The small plaque mutant of polyoma virus<sup>12</sup> was used throughout this investigation. Infection was carried out at input multiplicity of 100 P.F.U./cell. Unless otherwise stated, 4 day old cultures were infected. At this stage the cultures consisted of multinucleated fibres, myoblasts in the process of fusion and undifferentiated mononucleated cells.

In order to measure DNA synthesis in differentiated fibres, duplicates of infected and non-infected cultures were exposed to 2.5  $\mu$ Ci/ml. <sup>3</sup>H-thymidine (18,000 mCi./mmole) for 6 h at various times after introduction of the virus. The cultures were processed for autoradiography and stained for detailed cytological examination as previously described<sup>6</sup>.

DNA synthesis was not observed in multinucleated fibres exposed to virus for less than 30 h, as judged by

incorporation of tritium into their nuclei. More than 30 h after infection, however, an increasing proportion of the fibres were found to synthesize DNA. After 40 h as many as 15 per cent of the fibres had labelled nuclei. Usually when DNA synthesis was observed in a fibre all of the nuclei were found to have incorporated the labelled precursor (Fig. 1); however, fibres were found in which

Fig. 1. Autoradiograph of PV infected multinucleated muscle fibre. 4 day old cultures were infected with PV; 48 h after infection the cultures were exposed to  $^3\text{H}$ -thymidine for 6 h. Notice labelling of all nuclei in one fibre and absence of labelling in a neighbouring fibre ( $\times 300$ ).

Fig. 2. A, Dividing nuclei in a PV infected muscle fibre. Note gradient of progressive stages of mitosis: from non-dividing nuclei and early prophase (left) to clumping of chromosomes in late metaphase (right). Culture conditions and infection identical to those described in the legend to Fig. 1. Fixed at 72 h after infection and stained with Giemsa. ( $\times c. 275$ .) B, Portions of Fig. 2A at higher magnification ( $\times 1000$ ).

Fig. 3. Stages in the formation of abnormal giant nuclei after PV infections, as a result of aggregation and clumping of groups of chromosomes within the multinucleated fibres. Culture conditions and infection were identical to those described in the legend to Fig. 1. A fixed at 72 h, B and C at 82 h after infection. Stained with Giemsa. ( $\times c. 235$ ,  $\times c. 425$ ,  $\times c. 265$ .)

only a fraction of the nuclei was labelled. In the latter case the labelled nuclei were clustered in one section of the fibre.

Mitotic figures began to appear in multinucleated fibres about 50 h after infection. After 70 h about 30 per cent of the fibres contained nuclei in various stages of mitosis. In many such fibres advanced metaphases could be observed at one end of a group of dividing nuclei; distal to these nuclei progressively earlier stages of mitosis were observed which terminated with early prophase and resting nuclei (Fig. 2). In other fibres all the nuclei undergoing mitosis were found to be in metaphase.

Division of nuclei within the fibres did not proceed beyond late metaphase. Instead the fusion of several metaphase figures into large clumps of chromosomes was observed. This phenomenon was frequently associated with rounding of the fibres and loss of their elongated form. In cultures fixed 90 h after infection or later, fibres and rounded cells containing huge abnormal nuclei were frequently found (Fig. 3). These are most probably the result of the clumping of the dividing nuclei observed in earlier stages. Mitotic figures were not observed in fibres of uninfected cultures.

The appearance of mitotic figures within the infected fibres suggested that the observed incorporation of thymidine into nuclei of muscle fibres represented the synthesis of cellular type DNA. A more direct approach was taken to determine the nature of the newly synthesized DNA, however. Rat muscle cells were infected with PV and were exposed to  $^3\text{H}$ -thymidine after 24 h. After 72 h cells were collected and their DNA was extracted. This DNA was mixed with PV DNA labelled with carbon-14 and fractionated on a methylated albumin kieselguhr (MAK) column as previously described<sup>11</sup>. From the results (Fig. 4A and B) it can be seen that the newly synthesized DNA is mostly of cellular and not of viral origin. This observation is in accordance with previous ones made on X-irradiated PV infected rat embryo cells<sup>10</sup>.

In order to determine whether there is synthesis of infective particles in PV infected rat muscle cultures, the following assay was performed. At various times after infection duplicate cultures were frozen and their virus content was assayed by the plaque technique<sup>14</sup>. Virus titre 2 h after infection was  $3.1 \times 10^7$  and at 24, 72 and 120 h titres were  $3.0 \times 10^7$ ,  $2.1 \times 10^7$  and  $1.8 \times 10^7$  plaque forming units respectively. Although the synthesis of minute amounts of virus cannot be excluded by this method, we interpreted these data as showing that virus synthesis does not play a significant part in this system.

At the time of infection the cultures used in the present study were in the stage of cell fusion, that is, myoblasts were still joining the multinucleated fibres. It was found that the number of fibres induced by PV to synthesize DNA dropped considerably if infection was delayed by a few days. This may be caused by the impermeability or insensitivity of multinucleated fibres to PV. Thus the infection of the differentiated cells appears to occur via the introduction of nuclei of pre-infected myoblasts into the growing fibres.

Incorporation of  $^3\text{H}$ -thymidine into infected cultures in the first 30 h after infection was into mononucleated cells, although an occasional fibre was observed to contain a labelled nucleus among many unlabelled nuclei. Somewhat later, all nuclei in affected fibres were observed to be labelled. This suggests that the introduction of the virus had induced postmitotic nuclei to resume DNA synthesis. In other words, it appears that the effect of PV infection is an induction of DNA synthesis in post-mitotic cells rather than merely the prevention of the formation of a mitotic block. The few labelled nuclei within the fibres most probably originated from myoblasts which incorporated labelled thymidine during the 6 h exposure to the radioactive nucleoside, and subsequently joined the fibres<sup>3</sup>.

These findings indicate that the formation of multinucleated fibres is not necessarily associated with an irreversible change in the capacity of the nucleus to synthesize DNA and undergo mitosis. The fusion of dividing nuclei into abnormal clumps of chromosomes and subsequently the formation of giant nuclei may not be caused by aberrations in the chromosomes, but rather by the close proximity of many mitotic apparatuses within the same cytoplasm. There is also a possibility of interference of the contractile proteins of the specialized muscle cells with the formation of mitotic spindles. Formation of giant nuclei has been observed in artificially induced polykaryons<sup>15</sup>.

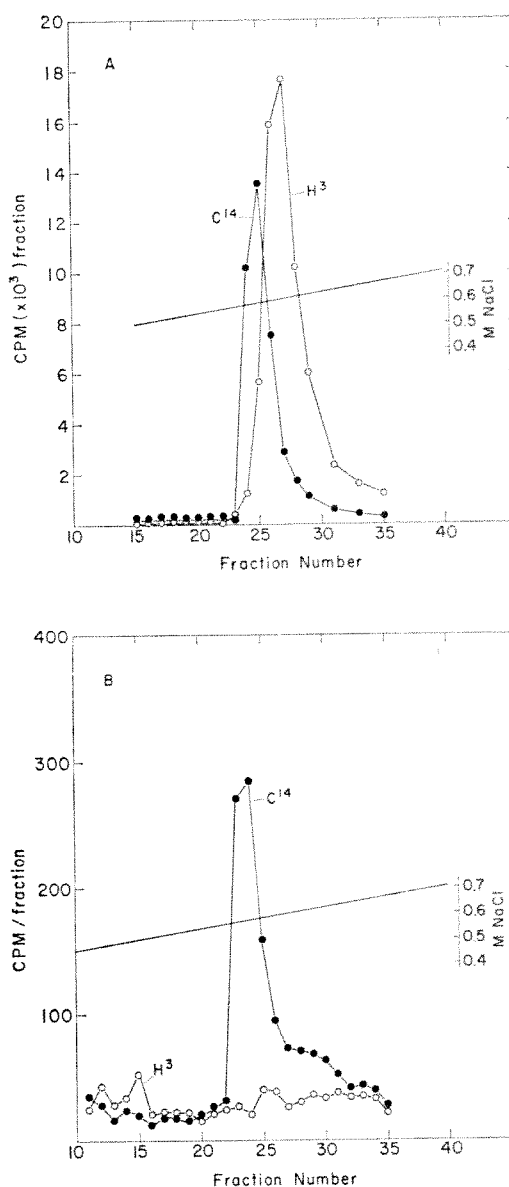

Fig. 4. MAK column chromatography of DNA from PV infected rat muscle cells 72 h after infection. The infected cultures were exposed to  $^3\text{H}$ -thymidine between 17 and 72 h post infection. A, Without heating. An aliquot of  $^3\text{H}$ -thymidine rat muscle cell DNA was mixed with PV marker DNA labelled with carbon-14 and chromatographed on an MAK column as previously described<sup>11</sup>. Recovery, tritium, 89.1 per cent; carbon-14, 96.8 per cent. B, With heating. The same mixture as used in A was boiled for 10 min in low salt concentration. After quick cooling in an ice bath, the mixture was chromatographed on the MAK column. Heat treatment was used because it had been shown for PV<sup>16</sup> that the heat-treated virus DNA eluted at the same salt concentration as native virus DNA, whereas there was practically no elution at this salt concentration of heat-denatured cellular DNA. Recovery, tritium, 0.55 per cent; carbon-14, 30.1 per cent. The lack of coincidence of the peaks of tritium and carbon-14 radioactivity in A and the extremely low recovery of tritium radioactivity in B indicate that the labelled DNA from the PV infected rat muscle cells is predominantly of cellular origin.

In most of the fibres which were induced to synthesize DNA, all the nuclei were synthesizing DNA and undergoing mitosis. Because the probability of infection of all the nuclei is very low, this phenomenon leads one to speculate that there are two possible mechanisms by which a few PV transformed nuclei within a fibre induce DNA synthesis and mitosis in all the nuclei: (a) by directly supplying the genetic information for the synthesis of proteins necessary for DNA synthesis and mitosis; (b) by producing a substance which suppresses the effect of an inhibitor of DNA synthesis present in normal multinucleated muscle cells.

## PHYSIOLOGY

### Entry of Ferritin into Human Red Cells during Hypotonic Haemolysis

A NUMBER of small molecules have been shown to enter red cells during hypotonic haemolysis. The membrane has been shown to be permeable to ATP (refs. 1, 2) and ghosts containing a number of organic compounds of metabolic interest, such as adenosine, cytidine, ATP and G6P, have been prepared<sup>3</sup>. The entry of dextran, with molecular weights from 10,000 to 250,000, into the red cell has been reported<sup>4</sup>, and albumin labelled with iodine-131 and haemoglobin labelled with iron-59 have been introduced into ghosts, and it was shown that these molecules could enter the cell only during haemolysis<sup>5</sup>. The red cell membrane is normally impermeable to these molecules, as well as to haemoglobin, and becomes impermeable again after release of haemoglobin, and so it is possible that the foreign molecules make their entry through the same channels which allow the escape of haemoglobin. The diffusion radius of haemoglobin is not less than 32 AU (ref. 6) and so the pores in the slightly stretched membrane of the haemolysing cell must be at least 64 AU in diameter during release of haemoglobin.

I have found that the protein ferritin with a molecular weight of 600,000 and a diameter of 100 AU will also diffuse across the membrane at the time of osmotic haemolysis and can be seen inside the ghosts in thin sections of a pellet of embedded ghosts. Red cells from a finger puncture were washed twice in isotonic saline and divided into three aliquots each of 0.1 ml. of packed cells. The cells of one aliquot were haemolysed with 5 ml. of phosphate buffer, pH 7, made 30 mmolar with distilled water and containing ferritin (Worthington, twice crystallized) in a concentration of 2 mg/ml. The second aliquot was treated in the same way, except that the ferritin was added to the hypotonic haemolysate 30 sec after the dilution with haemolysate. The third aliquot was not haemolysed, but 2 mg/ml. of ferritin was added to the

cell suspension. After 15 min at room temperature the cells of all aliquots were fixed in 1 per cent buffered osmium tetroxide, concentrated by centrifugation, dehydrated and embedded in 'Vestopal W'. Thin sections were examined in an RCA 'EMU3F' microscope without staining.

Fig. 1. Sectioned human red cell haemolysed in the presence of ferritin (2 mg/ml.) showing ferritin on both sides of plasma membrane. Unstained, fixed with osmium tetroxide, embedded in 'Vestopal'. ( $\times 195,000$ .)

The ghosts of the first aliquot showed ferritin molecules on both sides of the membrane (Fig. 1), and sometimes apparently within the membrane. Micrographs taken at high angle specimen tilt have not determined whether the ferritin is indeed within the membrane. Ferritin was seen only on the cell exterior in the pellet made from the second aliquot (Fig. 2). Results were the same in a modification of the treatment given to the second aliquot in which the ghosts were restored to an isotonic environment before the ferritin was added. The control cells (unhaemolysed, third aliquot) showed only some ferritin attached to the outside of the cell.

Fig. 2. Ferritin was added to the haemolysate 30 sec after haemolysis in 30 mmolar phosphate buffer. Ferritin is seen only on the exterior of the cell. Unstained, fixed with osmium tetroxide embedded in 'Vestopal'. ( $\times 195,000$ .)

In order to assess the role of electrostatic charge the experiment was repeated at a pH less than the isoelectric point of ferritin (pH 4.5), thus reversing the net charge on the ferritin from negative to positive. Net charge is most probably not a decisive factor because positively charged ferritin also penetrated the membrane.

In an attempt to set an upper limit on the pore size, colloidal gold (Matheson) with an average particle size of 250 AU was substituted for ferritin. The gold did not enter the cells (Fig. 3), indicating either that the pore diameter is less than 250 AU or that possibly the presence or absence of a protein coat on the probing particle is a crucial factor influencing entry.

It is well established that hypotonic haemolysis involves a prelytic swelling of the cell caused by the entry of water and that at a critical volume about 60 per cent greater than the initial volume haemoglobin escapes to a diffusion equilibrium with the external medium<sup>2</sup>. It is not at all certain whether the haemoglobin emerges through pre-existing pores which have been stretched, and, if so, whether these pores are the same pores which regulate water and small anion transport. The pore size for water transport in the normal cell was measured indirectly as 4 AU (ref. 7) and the total pore area was calculated to correspond to 0.01 per cent to 1 per cent of the cell surface area. Thus, there must be  $10^5$ – $10^8$  pores/cell. A single red cell contains about  $10^8$  molecules of haemoglobin, and so complete haemolysis must involve the passage of 1–1,000 molecules/pore. Fast rates of transport in the outward direction would be expected to have an inhibitory effect on entry, especially of large molecules. Thus the number of molecules such as ferritin entering the cell could be limited.

Fig. 3. Tangential cut through red cell membrane. Haemolysed in the presence of colloidal gold. The gold particles were never seen inside the ghosts. Unstained, fixed with osmium tetroxide embedded in "Vestopal". ( $\times 68,000$ .)

In an experiment designed to test this point the concentration of ferritin was varied in a 10:1 range. While the amount of extracellular ferritin seen varied approximately in the ratios added, the number of ferritin molecules seen inside the cells was little different for this range of concentrations, suggesting that some rate limiting factor was in effect.

Since this work was completed Seeman<sup>8</sup> has reported that, in agreement with our results, the red cell membrane is permeable to ferritin only at the time of haemolysis. He used mixtures of ferritin and colloidal gold (25–300 AU) and observed both kinds of particle inside cells if they were present in the haemolysate. In addition to the demonstration of the entry of ferritin and gold, Seeman demonstrated the existence of transient pores 300–500 AU in diameter in thin sections of the cells through which the ferritin presumably entered the cell. Reasons were given for believing that haemoglobin makes its escape through the same pores, although the possibility of other routes could not be excluded.

In summary, ferritin molecules have been shown to diffuse across the red cell membrane at the moment of release of haemoglobin, indicating a lower limit on pore size of at least 110 AU. Colloidal gold (250 AU) was excluded. Impermeability to ferritin immediately after haemolysis is indicative of a labile element in the membrane, in agreement with other results using smaller molecules, and with Seeman's results, also using ferritin.

### Transneuronal Cell Degeneration in the Olfactory Bulb shown by the Golgi Method

THE Golgi technique has been used extensively to investigate the detailed morphology of individual neurones in normal material of the central nervous system, but the lack of understanding of the principles which underlie the selective impregnation of only a few cells and the well known capriciousness of the method have tended to preclude its experimental application. This report concerns the change in the appearance of nerve cells and their processes shown by this method during the early stages of transneuronal degeneration. Cells in the olfactory bulb which have undergone this form of degeneration because of interruption of the olfactory afferent fibres do not impregnate as well with the Golgi method as the cells in the opposite normal bulb<sup>1</sup>, and when the pyramidal neurones in certain areas of the cerebral cortex are deprived of some of their afferent fibres they may show diminished impregnation of either their finer dendritic branches or of a proportion of their spines<sup>2–4</sup>. In most of these investigations the appearance of the cells has been studied after relatively long survival periods, and there is little evidence<sup>5</sup> to indicate the time of onset of these changes and how they are correlated with the observations made in sections stained by the Nissl and reduced silver method.

The impregnation of the constituent neurones of the olfactory bulb has now been studied in rabbits at varying intervals after unilateral removal of the olfactory mucosa. The rabbits were operated on at the age of 6 weeks, and two animals were killed at each of the survival times. Ten days after operation there is little difference between the olfactory bulbs of the two sides, but by 17 days a striking difference has developed; very few mitral, tufted and periglomerular cells are seen on the operated side, and those that are present are scattered over the entire cross-sectional area of the bulb. The characteristic dense felt-work of dendrites and recurrent collaterals in the external plexiform layer is almost completely absent on the operated side. The difference in impregnation of the mitral cells is also clearly shown in the accessory bulb. The same changes are found at survival periods of 24, 32 and 49 days, and the only mitral cells found on the operated sides of these brains are in small groups, usually in the ventro-lateral parts of the bulbs, subjacent to where

some of the olfactory fibres are preserved. At these longer periods the bulb as a whole is considerably shrunken, and a new type of cell is found at the level of the mitral cell layer. The soma of this cell is the same size as a mitral cell, but it has numerous fine, irregular processes on both its superficial and deep aspects. It is difficult to determine whether this cell is glial in nature or an altered mitral cell. At all these survival times the unimpregnated periglomerular, tufted and mitral cell bodies can be readily stained, on the same Golgi section, with thionin, and in other Bodian-stained material the dendrites of these cells, although attenuated, are clearly seen. In many of the experiments involving long survival the neurones of the anterior olfactory nucleus and of the pyriform cortex on the operated side show a less extensive dendritic arborization. The reasons for considering that these changes are the result of the experimental denervation and not simply an expression of the unreliability of the Golgi method have already been discussed<sup>1</sup>.

These findings confirm the earlier observations that cells undergoing transneuronal degeneration in the olfactory bulb are more resistant than normal cells to impregnation with the Golgi method, and extend them in showing that this change in reaction to the Golgi impregnation occurs at the same time as shrinkage of the cell body becomes evident in sections stained with the Nissl method. In the olfactory bulb the absence of staining, either of the neurone as a whole or of the dendritic branches, does not mean that these cells or processes have been lost, for the cell-bodies of the affected neurones can be demonstrated with the Nissl stain, and their dendrites with the Bodian method. In the pyriform cortex, where Golgi material showed a marked loss of dendritic spines after interruption of afferent fibres from the olfactory bulb, electron microscopy showed the persistence of the spines even in association with degenerated presynaptic endings<sup>5</sup>. It is possible, therefore, that the dendritic spines in other areas of the cerebral cortex which do not impregnate with the Golgi method after partial deafferentation<sup>4</sup> are also not lost but are altered so that they do not react. The basis for this change in staining properties is not known, but may be elucidated by electron microscopic studies of transneuronal cell degeneration, and this in turn may provide an explanation for the selective impregnation of normal neurones.

### Growth Characteristics of Mouse Thymus in the Neonatal Period

ALTHOUGH renewed efforts have been made towards an understanding of the function(s) of the thymus, the exact mechanisms involved remain unclear. It is not known whether the thymus serves primarily as a source of immunologically competent cells, or whether it produces a substance or substances and/or contact factors which may control proliferation and immunological maturation of peripheral lymphoid cells. Combinations of such suggestions have been made repeatedly<sup>1,2</sup>. A meaningful evaluation of the existence and magnitude of thymic cell migration during the perinatal period of life requires more information on at least the following thymic growth characteristics as a function of age before and after birth: (a) the rate of thymic growth; (b) proliferative activity of thymic lymphoid cells; (c) the generation time of thymic lymphoid cells; and (d) a quantitative estimate

of intrathymic cell death. We report here an investigation of growth and proliferative activity of the thymus of mice ranging in age from 3 days before to 6 days after birth.

Specific pathogen-free Swiss albino mice (Hale-Stoner strain) of both sexes were used. Mating time was limited to 8 h to allow a more accurate estimate of the gestation time. One pregnant female in each cage was allowed to deliver on term and served as a reference for determination of the age of foetuses killed before birth. Tritiated thymidine (specific activity 1.9 c./mmole, diluted in buffered saline, pH 7.4, to contain 100  $\mu\text{C}/\text{ml}$ .) was administered as a single intra-abdominal injection of 0.5  $\mu\text{C}/\text{g}$  of body weight. Injections were given to four animals in each age group 3, 2 and 1 day before birth (0.5  $\mu\text{C}/\text{g}$  of body weight of tritiated thymidine given to the mother by the intra-abdominal route), immediately after birth, and 1, 2, 3, 4, 5 and 6 days after birth. The animals were killed with ether 30 min after the injection of tritiated thymidine. The thymus was removed and minced in a drop of normal mouse serum. Smears were made with a fine brush. The air-dried preparations were fixed in absolute methanol for 10 min, dipped in liquid 'NTB-2' emulsion (Kodak, Rochester, New York), and exposed at 4°C in dehumidified air for 51 days. The developed preparations were stained with buffered Giemsa solution, 1:100, pH 6.0. An average of 1,000 cells was evaluated from each mouse. Lymphoid cells were classified according to their morphological and tinctorial characteristics as described previously<sup>3</sup>. Mitotic figures were recorded separately. As a correction for background, only cells with four and more grains were considered to be labelled. In a total of 260 additional

animals (from twenty to thirty in each age group), wet weights of thymus were recorded.

Wet thymic weights of mice aged from 4 days before to 6 days after birth are given in Fig. 1. Thymic weights increased at a steady rate from 4 to 1 day before birth; from that time thymic weights continued to increase steadily but apparently at a diminished rate. Calculation of regression lines based on logarithmically transformed individual weight measurements (Fig. 2) made it possible to test whether or not the relative weight increase before birth (group 1) was statistically different from that observed after birth (group 2). Based on the slopes of the regression lines we calculated that before birth thymic weights increased daily by a factor of 1.911 (95 per cent confidence limits, 1.812, 1.996) whereas the relative daily weight gain after birth was 1.195 (95 per cent confidence limits, 1.189, 1.208). A *t* test on these two figures showed that the difference was very significant ( $P < 0.001$ ). An analysis of variance of the two regressions proved both to be linear to a significance level of 1 per cent (Table 1). The body weights measured in similar age groups did not allow the calculation of linear regressions, and so the increase in body weight could not be directly compared with that of thymic weight.

The number of mitotic figures counted in 1,000 thymic lymphoid cells for each age group before and after birth is plotted at the top of Fig. 3. Throughout the period of observation the number of thymic cells in mitosis ranged from nine to thirteen/1,000 cells with the exception of a

peak number of mitotic figures of seventeen and nineteen/1,000 cells at 3 and 4 days, respectively. Combined initial labelling indices of all classes of thymus cells are shown in the middle part of Fig. 3. The overall labelling index did not fluctuate appreciably from 3 days before to 2 days after birth: from 8 per cent to 11 per cent of thymic cells contained four grains or more. Three and four days after birth, however, initial labelling indices of almost 20 per cent were observed, with a reduction to about 15 per cent on days 5 and 6. Overall mean grain counts of initially labelled thymic lymphoid cells with four grains or more are shown at the bottom of Fig. 3. Mean grain counts remained at less than twenty grains/labelled cell up to the age of 2 days. An increase to thirty and forty-eight grains/labelled cell was noted 3 and 4 days after birth. Two days later, the mean grain count had diminished to twenty grains. These data show that the thymic growth rate decreases sharply immediately before birth, and that a marked increase in the relative proportion of proliferating cells was observed after 3–4 days without a concomitant increase in the weight of the organ.

The observation of a prenatal change in the rate of growth of the thymus is consistent with and extends the findings of Ball<sup>4</sup>, who investigated the total number of thymic lymphoid cells in a limited number of mice of different age groups (3–10 mice/group) with the aid of a Coulter counter. He found that the total lymphoid cell population increased approximately ten-fold between 4 and 2 days before birth: after a short stationary period, only a five-fold increase in the total number of cells was noted between 2 and 14 days after birth. This break in the weight curve of the thymus<sup>5</sup> can be explained by (a) an increased migration of cells out of the thymus; (b) a prolongation of the mean generation time of proliferating lymphoid cells in the thymus; (c) a diminished influx of cells; (d) a rate of intrathymic cell death after birth which is greater than that occurring before birth; or (e) two or more of these possibilities combined.

In evaluating the autoradiographic data the possibility has to be considered that a certain number of actively proliferating cells with a low labelling intensity may have been missed because of the relatively low specific activity of the injected tritiated thymidine; the same small doses were used in a later experiment for multiple injections and permitted thus to remain below concentrations causing radiation damage. Autoradiographic inefficiency may have been another reason for missing weakly labelled cells, for only cells with four and more grains were considered to be labelled. Fig. 2 shows that with a progressive background correction the shape of the curve did not change appreciably. On the other hand, during the proliferative peak 3–4 days after birth the number of cells in mitosis increased from ten/thousand to nineteen/thousand cells, while the number of cells incorporating tritiated thymidine initially, at the same time, increased from 10 to 18 per cent. This clearly indicates that at that particular time only a small percentage of cells could have been missed as being unlabelled because of autoradiographic inefficiency. It therefore seems justified to say that a greater number of thymic lymphoid cells were in proliferation 3–4 days after birth than at any time during the period of observation. Although on brush preparations no distinction could be made between cells of cortical and medullary origin it may be assumed, nevertheless, that most of the proliferation takes place

Fig. 3. Top, number of mitotic figures/1,000 cells of mouse thymus in relation to age. Middle, initial labelling indices of thymic cells in relation to age (progressive background correction:  $>1$  = two and more grains;  $>2$  = three and more grains;  $>3$  = four and more grains;  $>4$  = five and more grains). Bottom, mean grain counts of initially labelled thymic cells (four and more grains) in relation to age.

in the thymic cortex as visualized by autoradiography of histological sections and because of a cortex : medulla ratio of 9 : 1.

No change in the thymic weight curve was observed during the peak in proliferative activity. The following explanations may apply: (a) an increased migration of unlabelled small lymphoid cells out of the thymus causes a relative increase of initially labelled medium and large cells; (b) an increased rate of intrathymic cell death compensates for increased proliferation; or (c) a postnatal increase in generation or mitotic time of thymic lymphoid cells explains the unchanged growth rate at a time of increased proliferation. A combination of any of these explanations could be the answer, and discussion has to await further results.

## Organization of Somatic Afferents to the Diencephalon

THREE main areas within the diencephalon are known to be concerned with somatosensory mechanisms; these are the ventrobasal complex, the intralaminar complex, and the posterior group. It is generally accepted that the afferents to the ventrobasal complex are organized in a simple somatotopic fashion<sup>1,2</sup>, whereas the input to the intralaminar complex<sup>3,4</sup> and to the posterior group<sup>4,5</sup> is non-somatotopic and generally of long latency. The arrangement of afferents to the ventrobasal complex may be more complex than previously supposed<sup>6,7</sup>, and the lateral thalamic nuclei may also be involved in somatosensory activity<sup>7</sup>. Furthermore, the properties of the nuclei of the dorsal column show a rostro-caudal differentiation<sup>8,9</sup>, and it has been suggested that this is reflected in a differential termination of the medial lemniscus<sup>10</sup>. We have investigated the distribution of degeneration in the rat diencephalon using the Nauta method<sup>11,12</sup> after lesions made separately in the gracile and cuneate nuclei, the spinal cord at different levels from the spinomedullary junction to the lumbar region, and the trigeminal nuclear complex.

The projection from the caudal half of the nuclei of the dorsal column conforms to the classical distribution of the medial lemniscus, except for a small projection to the contralateral medial (magnocellular) part of the medial geniculate complex. Within the contralateral ventrobasal complex pars externa the lemniscus is distributed in a topographical pattern corresponding to the somatotopy

Fig. 1. Scheme of afferents to the rat ventrobasal complex as viewed from above. The curving hatched line represents the boundary between the arcuate (Arc) and external (Ext) parts of the complex (A). The distribution of fibres from the nucleus gracilis and nucleus cuneatus is shown. The representation of afferents from the trigeminal nuclei (N.V.) is drawn to emphasize the difference between the subnucleus caudalis and the other subnuclei. B shows the projections from the spinal cord. The first cervical to sixth thoracic (C1-T6) and seventh thoracic to coccygeal (T7-Co) segments project rostrally. All segments (C1-Co) have an additional projection caudally, but this arises largely in the first two cervical segments.

revealed by the evoked potential method<sup>6</sup> (Fig. 1A). The projection from the rostral half of the nuclei of the dorsal column to the ventrobasal complex is organized similarly. In each case axosomatic endings are found. In addition, an unorganized projection from the rostral parts of the nuclei of the dorsal column ends contralaterally in the medial part of the medial geniculate complex, in the deep part of the anterior pretectal nucleus, in the zona incerta and in the dorsal part of the posterolateral thalamic complex. With the exception of the zona incerta all these regions also receive fibres from the spinothalamic tract which in addition distributes diffusely to the nucleus centralis lateralis and the lateral part of the nucleus medialis dorsalis. Within the ventrobasal complex the pattern of termination differs from that of the medial lemniscus in that the spinothalamic tract ends predominantly in the rostral one third of the complex, although showing the expected mediolateral topography (Fig. 1B), and the endings are not axo-somatic. Each segment of the cord also projects to the caudal part of the ventrobasal complex in an area restricted almost entirely to the field of distribution of the nucleus gracilis (Fig. 1B). This latter projection, however, arises largely in the first two cervical segments, but shows some slight evidence of topographical ordering with more caudal segments projecting ventrally. Lesions restricted to the dorsal horn of the second and third cervical segments do not reveal the more heavy (cervical) component of this projection, and so it is thought to arise in the lateral cervical nucleus. These same most cranial two segments also send a very small projection to the parafascicular-centrum medianum complex, ending predominantly in its dorsolateral part. Degeneration in this complex after high cervical cordotomy has been attributed to damage to the subnucleus caudalis of the trigeminal nucleus<sup>13</sup>, but we have failed to produce such degeneration by making lesions confined to either the subnucleus caudalis or to the second and

third segment dorsal horns. This projection has also been considered to be to the most caudal parts of the nucleus centralis lateralis and not to the parafascicular-centrum medianum complex proper<sup>14</sup>. Our results are largely, but not completely, in accord with this explanation. We have found no evidence of a projection from any of the above systems to the homologue of the posterior group, unless the posterolateral complex and medial part of the medial geniculate complex are included in this term. The rat posterior group (in the narrow sense of the term) does, however, appear to receive fibres from the medullary and pontine reticular formation. In no experiment have we found degeneration in the thalamic reticular nucleus.

It is widely accepted that the spinothalamic system has two components, only one of which reaches the ventrobasal complex. It is now clear that the same is true of the dorsal column-medial lemniscus system, although the diencephalic distribution of the extra-ventrobasal components of the two systems is not identical. While the observation that all parts of the dorsal column nuclei send afferents to the ventrobasal complex is interesting (in view of their afferent functional subdivision<sup>8</sup> and the fact that the properties of ventrobasal neurones are not identical with those of neurones in any part of the dorsal column nuclei<sup>15</sup>), even more striking is the complexity of organization of the long afferents to the ventrobasal complex we have revealed. The caudal distribution of the afferents from the spinal cord which we believe to arise partly in the lateral cervical nucleus is compatible with observations in the cat<sup>16</sup>, and this region of the rat ventrobasal complex appears to be that in which a "second somatic sensory area" has been described<sup>6</sup>. In the cat this area may correspond at least in part to the "zone of convergence" of dorsal column-medial lemniscus and spino-cervico-thalamic activity in the posteroventral nucleus<sup>7</sup>. The extension of this zone into the lateral thalamic complex is compatible with our findings. The differential distribution of the direct spinothalamic system within the ventrobasal complex has not been noted in primates<sup>13</sup>, and although a rostrocaudal organization has been described in the cat<sup>17</sup> it does not at all correspond with our findings. Further work must determine whether these species differences are real. Our present work suggests that any differences in the mechanisms of cutaneous sensibility in different species are reflected in a changing pattern of organization of the spinothalamic system rather than of the medial lemniscus.

## Projection to the Spinal Cord from the Medial and Descending Vestibular Nuclei of the Cat

THE principal projection from the vestibular nuclei to the spinal cord of the cat is the vestibulospinal tract, which originates in Deiters's nucleus<sup>1</sup>, but fibres from the vestibular nuclei also reach the cord through the descending medial longitudinal fasciculus (MLF). There is uncertainty concerning the origin of this bundle: some authors have suggested that some of its fibres originate in the medial and descending nuclei<sup>1</sup>, while others believe that the descending nucleus does not contribute to this projection<sup>2</sup>. Many descending MLF fibres may be branches of dichotomizing axons, the other branch of which enters the ascending MLF<sup>1</sup>. The descending MLF fibres terminate in parts of lamina VII and lamina VIII of the spinal cord<sup>2</sup>, but their exact connexions and function are not known; impulses in the descending MLF may produce depolarization of primary afferent terminals, perhaps by relays through propriospinal pathways<sup>3</sup>.

In the present experiments we have recorded from cells in the medial and descending vestibular nuclei in acutely decerebellated cats anaesthetized with chloralose-urethane, paralysed with 'Flaxedil' and artificially respired. Throughout the experiment the expired carbon dioxide was maintained at normal physiological levels and the blood pressure was maintained above 80 mm mercury. The stimulating and recording equipment and much of the dissection and preparation of the animal were as previously described<sup>4</sup>. The descending MLF was antidromically stimulated by an array of two concentric steel electrodes. The protruding inner electrode was inserted perpendicular to the spinal cord near the midline at C3 so as to lie near the fibres which are along the anterior median fissure<sup>5</sup>. The ascending MLF was also antidromically stimulated by a similar electrode array, inserted at an angle of about 45° into the midline of the floor of the fourth ventricle, about 2 mm rostral of Deiters's nucleus. Stimuli to the membranous labyrinth were delivered through a fine platinum ball electrode, inserted as deeply as possible towards the ipsilateral fenestra vestibuli and held in place with dental cement. Glass micropipettes, filled with 2 molar sodium chloride saturated with fast green FCF and selected for initial resistances of 2-5 megohms, were used to record the activity of single units extracellularly and to mark the position of the electrode tip<sup>6</sup>; a mark was made in almost every track. Numerous tracks were made over the whole extent of the medial nucleus (except for its rostralmost tip) and in the descending nucleus, usually within 400  $\mu$  of its border with the medial nucleus. Cells were found by searching in the nuclei while stimulating the ascending and descending MLF at a rate of 5 stimuli/sec. Antidromic impulses were identified by their fixed latency at varying strengths of stimulation, by their response to high frequency stimulation and by collision with spontaneous impulses<sup>4</sup>. It was often easy to determine from the shape and size of the potentials whether responses evoked by stimulation of different inputs were those of the same unit. In questionable cases the identity of the doubtful response was tested by attempting to produce collision block of a known antidromic response (Fig. 1B). At the end of the experiment the animal was perfused and the brain stem was removed, fixed, sectioned serially at 100  $\mu$  on a freezing microtome and stained for cells and fibres<sup>6</sup>. The position of the cells in each track was estimated from the location of the mark in that track.

290 cells, with spike amplitudes ranging from 50 to 1,000  $\mu$ V, have been studied in thirteen experiments. Of 146 medial nucleus cells tested with the descending MLF stimulus, 24 (16 per cent) were activated with latencies ranging from 0.5 to 2.2 msec and hence projected into the descending MLF. In contrast, 85 of 211 (40 per cent) medial nucleus cells projected into the ascending MLF.

Fig. 1. Responses of cell located in the rostral half of the descending nucleus, 200  $\mu$  from its border with the medial nucleus. A, This unit does not respond to stimulation of the ascending medial longitudinal fasciculus (MLF), but is antidromically driven by stimulation of the descending MLF (DMLF). B, The cell is fired monosynaptically by stimulation of the labyrinth (LAB). The stimulus is near threshold, and in the lowest sweep the cell fails to fire; the LAB stimulus produces only a focal potential, and the DMLF stimulus evokes an antidromic response. In the two upper sweeps LAB stimulation evokes a monosynaptic response on top of the focal potential and the DMLF response is blocked by collision. Calibration, 500  $\mu$ V; time, 1 msec. Upward deflexion negative.

Although cells with axons in the descending MLF were found throughout the medial nucleus, eighteen out of twenty-four were found rostral to its mid-point. Cells were found dorsally, ventrally, medially and laterally and in each of the quadrants the fraction of units driven antidromically by the cord stimulus was similar to the fraction driven antidromically in the population as a whole. In the area of the descending nucleus which we explored, nine out of thirty-one cells had axons in the ascending MLF and thirteen out of twenty-five units projected into the descending MLF (antidromic latencies, 0.9–2.0 msec). The response of one of the latter units is shown in Fig. 1. Of all units projecting to the spinal cord, five of twenty-two medial units and three of twelve descending units were also invaded antidromically as a result of a stimulus to the ascending MLF. While it is very likely that not all axons, ascending and descending, were activated by our stimuli, this finding suggests that many of the axons of cells in the medial and descending nuclei projecting to the spinal cord are not branches of dichotomizing fibres.

Many units in the medial and descending vestibular nuclei were fired by stimulation of the ipsilateral labyrinth at a repetition rate of 1/sec. Of the total sample, 36 per cent (62/171) of the medial and 40 per cent (12/30) of the descending cells were fired monosynaptically (Fig. 1) at a latency, to strong shocks, of 0.9–1.5 msec after the stimulus artefact<sup>7,8</sup>. Most driven cells responded once to every stimulus. Of the medial cells with axons in the ascending MLF, 30 per cent (18/61) were monosynaptically activated by stimulation of the labyrinth. Of the medial cells that could not be identified antidromically but were found because they were firing spontaneously, 14 per cent (7/51) were monosynaptically activated. In contrast, labyrinthine stimulation caused monosynaptic firing of 73 per cent (16/22) of those medial nucleus units, and 64 per cent (7/11) of those descending nucleus units with axons in the descending MLF. Many medial (55/153) and descending (17/32) cells were driven polysynaptically by stimulation of the labyrinth; a few of these cells also responded monosynaptically. But only three out of twenty-one medial and four out of twelve descending units antidromically activated from the descending MLF were polysynaptically fired by stimulation of the labyrinth. The units projecting to the cord as a group therefore received a particularly marked monosynaptic input from the labyrinth. These results are similar to those obtained with Deiters's units projecting to the cervicothoracic cord by way of the vestibulospinal tract: while 51 per cent (31/61) of these cells were monosynaptically driven from the labyrinth, only 5 per cent (3/61) were driven polysynaptically<sup>8</sup>.

The results of our experiments confirm anatomical findings<sup>1,2</sup> and show that the medial and lateral parts of the medial vestibular nucleus send fibres to the spinal cord in the descending MLF and that this projection is a modest one compared with both the spinal projection of the lateral vestibular nucleus and the ascending projection of the medial nucleus. It is quite certain that the medial part, at least, of the descending nucleus also contributes to the descending MLF. This system, considered by all authors to reach no further caudally than the mid-thoracic cord<sup>1,2</sup>, has a strong direct input from labyrinthine receptors. This finding, together with our previous report that the cervicothoracic component of the vestibulospinal tract is relatively more subject to labyrinthine control than the lumbosacral component<sup>8</sup>, provides an explanation for observations that the motor activity of the cervicothoracic cord is more influenced by the labyrinth than the motor activity of the lumbosacral cord<sup>1</sup>.

### Effect of Tetrodotoxin on the Electrical Activity of the Smooth Muscle of the Vas Deferens

THE action potentials of vertebrate smooth muscles differ from those of nerve and fast skeletal muscles in several ways. For example, replacement of up to 80 per cent of the sodium salts of the bathing solution with sucrose has little or no effect on the action potential<sup>1</sup>. Provided that allowance is made for the possible redistribution of Na<sup>+</sup> ions in a low Na<sup>+</sup> environment and if it is assumed that relatively few channels are available for the inward movement of Na<sup>+</sup>, it is possible to account for this finding in terms of the ionic theory of Hodgkin and Huxley<sup>2</sup>. On the other hand, the slow rate of depolarization of the spikes of the taenia coli<sup>3</sup>, vas deferens<sup>4</sup> and uterus<sup>5</sup>, and the graded nature of the spikes in response to electrical stimulation<sup>3,4</sup>, are characteristics which resemble the properties of crustacean skeletal muscle. Fatt and Ginsborg<sup>6</sup> have shown that the spike mechanism in crustacean muscle involves an increase in conductance for divalent cations rather than Na<sup>+</sup> ions. It has been suggested that Ca<sup>++</sup> ions may also be involved in the action potentials of smooth muscle<sup>7</sup>.

The puffer-fish poison, tetrodotoxin, does not block the spikes of crayfish muscle<sup>8</sup> and evidence is accumulating that this toxin acts specifically on the voltage dependent increase in Na<sup>+</sup> conductance which is characteristic of cells specialized for the conduction of excitation<sup>9</sup>. It was of

interest therefore to study the action of tetrodotoxin on smooth muscle. The vas deferens was used for the present experiments because, despite its dense innervation, individual cells are electrically excitable and many cells respond to intracellular stimulation with self-regenerative spikes<sup>4</sup>.

Test solutions of tetrodotoxin were freshly prepared from stock solutions which were made by dissolving the buffered toxin obtained from Sankyo (Tokyo) in distilled water. Stock solutions were kept at about 5° C for no longer than one month. The potency of the toxin was tested by determining the concentration which blocked the action potential of toad skeletal muscle ( $10^{-7}$  g/ml.).

Isolated preparations of vas deferens supplied by the hypogastric nerve were dissected from guinea-pigs and mice which had been stunned and bled out. Preparations were mounted in a constant temperature bath (35° C) which was perfused with a modified Krebs solution, as previously described<sup>4</sup>.

A single micro-electrode was used to pass current and to record the membrane potential of individual smooth muscle cells by means of the bridge circuit described by Martin and Pilar<sup>10</sup>. The voltage displacement due to current flow across the membrane could be distinguished from that due to the electrode tip by the relatively long membrane time constant of the smooth muscle cell (2–6 msec).

Fig. 1A shows a typical spike in response to intracellular stimulation with a current of 1.7 n.amp. Fig. 1B was recorded from the same preparation (guinea-pig vas deferens) after exposure to tetrodotoxin,  $10^{-7}$  g/ml. for 40 min. At this time the response to nerve stimulation was completely blocked.

Fig. 1. Action potentials in response to intracellular stimulation (lower traces) by current pulses (upper traces) recorded from a preparation of guinea-pig vas deferens; record A taken in normal solution, and record B after 40 min exposure to tetrodotoxin  $10^{-7}$  g/ml.

In normal conditions the amplitude and time course of the spikes in response to intracellular stimulation vary from cell to cell. The currents needed to elicit spikes of maximum amplitude (up to 75 mV) also vary, probably due to the non-uniformity of the dimensions of individual cells and the variable position of the micro-electrode<sup>4</sup>. It was not always possible to maintain an impalement for long enough to compare the spikes recorded in the same cell before and after tetrodotoxin. The characteristics of smooth muscle cells impaled in the presence of the toxin were, however, indistinguishable from those of normal cells. Self-regenerative spikes—spikes which continued to develop after the cessation of the current pulse—were just as common in the presence of the toxin as in control experiments. The concentrations of toxin studied in these experiments (up to  $10^{-6}$  g/ml.) did not appear to have any

Fig. 2. Effect of tetrodotoxin,  $10^{-7}$  g/ml., on spontaneous junction potentials and junction potentials in response to intramural nerve stimulation (white dots) recorded from a preparation of mouse vas deferens. Record A taken in normal solution, records B, C and D, 3 min, 5 min and 11 min after exposure to the toxin. Note the increase in frequency of the spontaneous junction potentials in record D.

effect on the electrical excitability of either mouse or guinea-pig vas deferens.

Thus the action of tetrodotoxin on these smooth muscles is similar to its action on muscles which normally give graded responses to stimulation<sup>9</sup>. It may be tentatively concluded that an increase in  $\text{Na}^+$  conductance is not essential for spike generation. The vas deferens is, however, a densely innervated tissue and conduction of excitation from cell to cell probably does not occur in normal circumstances. It may be that an  $\text{Na}^+$  mechanism is involved in the generation of action potentials in other smooth muscles where conduction occurs over long distances (for example, the ureter).

Fig. 2 shows the effect of tetrodotoxin ( $10^{-7}$  g/ml.) on the junction potentials recorded from a preparation of mouse vas deferens. Fig. 2A, recorded in normal solution, shows a series of junction potentials in response to stimulation of intramural nerve fibres, together with spontaneous junction potentials occurring in the absence of nerve stimulation. In this experiment the strength of nerve stimulation was just above threshold and the junction potentials were too small to trigger action potentials. Fig. 2B was recorded 3 min after exposure of the test solution at a time when the response to nerve stimulation was failing. In Fig. 2C, 5 min after exposure, the junction potentials were completely blocked. The spontaneous junction potentials persisted in the presence of tetrodotoxin, however, and 11 min after the response to nerve stimulation was blocked their frequency was markedly increased (Fig. 2D). It is interesting that a similar increase in the frequency of miniature end-plate potentials was observed by Kao and Nishiyama<sup>11</sup> in experiments on the frog skeletal neuromuscular junctions in the presence of saxitoxin which also has a specific blocking action on  $\text{Na}^+$  conductance.

In order to test whether blockade of transmission by tetrodotoxin in the vas deferens resulted from failure of the nerve impulse, action potentials were recorded from the hypogastric nerve. The proximal and distal ends of the nerve were held in oil for stimulating and recording respectively, while the central portion was immersed in modified Krebs solution to which the toxin was added in concentrations ranging from  $10^{-7}$  to  $10^{-5}$  g/ml. The B fibre elevation and part of the polyphasic C fibre elevation were rapidly blocked. This effect was reversible provided that the nerve was exposed to the drug for only a few minutes. Part of the C fibre elevation was, however, somewhat resistant to the toxin. The nature and origin of these toxin resistant C fibres remain to be established.

Because tetrodotoxin is able to block the response to nerve stimulation without affecting the response of the smooth muscle of the vas deferens to transmitter or its electrical excitability, tetrodotoxin is likely to prove a useful tool for further studies on the transmission

of excitation at this autonomic nerve smooth muscle junction.

### Rapid Movement of Epinephrine and Norepinephrine into Human Erythrocytes

HUMAN erythrocytes are permeable to many substances such as catechol, *p*-phenylenediamine and sulphanilamide<sup>1</sup>. Knowledge about the entry of the catecholamines into erythrocytes was the objective of the present study. The technique used required incubation of freshly drawn heparinized human blood with a radioactive catecholamine for various periods of time. Ultrafiltration was used because of the poor recovery of unchanged epinephrine and norepinephrine during chemical deproteinization procedure in red cells.

Radioactive epinephrine or norepinephrine hydrochloride, with tritium attached to the proximal carbon on the side chain, was used. One-tenth ml., containing 0.4 mc. and 0.011  $\mu$ g of epinephrine, was added to 4 ml. of blood and 4.0 ml. of 0.1 molar sodium phosphate buffer of pH 7.4 at zero time. Typically, 4.1 ml. of blood containing the radioactive epinephrine was incubated in a water bath at 37° C. The blood was then centrifuged at approximately 2,500 r.p.m. for 1 min. The separated cells were haemo-

lysed in boats made of aluminium foil, which were placed into liquid nitrogen. An equal volume of water was added to the thawed cells to facilitate handling.

Ultrafiltration was performed (Fig. 1) in cellulose tubing 4 in. in length and 0.25 in. in diameter<sup>2</sup>. To 10 ml. of a scintillation solution was added 0.1 ml. of the ultrafiltrate plus either 0.1 ml. of water or 0.1 ml. of the epinephrine standard. Scintillations were counted for 10 min in a Packard 'Tri-Carb' liquid scintillation spectrometer. Duplicate counts were in agreement within 1 per cent in every instance.

The cellulose tubing was not equally permeable to epinephrine and to water. Regardless of whether the tubing contained a sodium phosphate solution, plasma or haemolysed erythrocytes, the concentration of the radioactivity within the sac was 1.91 times greater than that in the ultrafiltrate. No catecholamine could be separated from the cellulose membrane by soaking or vigorous washing during any phase of the study. Background counts in the absence of added radioactivity were negligible. Duplicate ultrafiltrations of different portions of the same aqueous plasma or cell specimen yielded agreement within 6 per cent in each instance.

The total radioactivity in the plasma or cell layer was determined by multiplication of the scintillation count in 0.1 ml. of the respective ultrafiltrate by 1.91, as well as the volume of the solution undergoing ultrafiltration. Subtraction of the contribution of the 11 per cent of the total plasma remaining in the erythrocyte layer yielded the radioactivity associated with the cells alone. The use of the conversion factor, 1.91, permitted agreement within essentially 100 per cent between the total amount of radioactivity added, as determined in aqueous solution, and the total amount recovered after the ultrafiltrations. The catecholamines were not adsorbed on the erythrocyte walls, because the same counts were found in the ultrafiltrates of haemolysed red cells before and after removal of the erythrocyte ghosts by centrifugation<sup>3</sup> at 12,000g for 30 min.

Incubation of epinephrine with 4 ml. of blood from 120 different human beings yielded ratios of distribution of radioactivity between cells and plasma which differed by no more than 20 per cent from each other, for each time interval tested. The distribution of epinephrine between the erythrocytes and plasma of a typical specimen of blood (haematocrit 45) for various periods of incubation at 37° C is given in Table 1. In the absence of incubation at 37° C, epinephrine could enter the cells during the 90 sec of centrifugation and manipulation of the blood at room temperature. The distribution of epinephrine was expressible as the ratio of its concentrations in the cell water ( $C_e$ ) and plasma ( $C_p$ ) (Table 1). The water content of red cells was found to be 72 per cent (w/v)<sup>4</sup>.

Fig. 1. Diagram of the ultrafiltration apparatus.

Table 1. DISTRIBUTION OF RADIOACTIVE EPINEPHRINE BETWEEN ERYTHROCYTES AND PLASMA OF HUMAN BLOOD

Minutes of incubation of blood at 37° C	Per cent epinephrine in plasma	Per cent epinephrine in cells	$C_e/C_p$
0	75	25	0.60
1	69	31	0.80
3	63	37	1.04
30	62	38	1.09

In each instance, the recovery of radioactivity after passage of the ultrafiltrate through an aluminium oxide column at pH 8.4, followed by elution at pH 3.5, exceeded 80 per cent. This behaviour was typical of epinephrine. In contrast metanephrine was not adsorbed on aluminium oxide<sup>5</sup> and adrenochrome was not eluted at pH 3.5. Oxygenation of the blood, defibrination by stirring, or anticoagulation by (ethylenedinitril) tetra-acetic acid, disodium salt, did not change the results. The findings for norepinephrine-<sup>3</sup>H were essentially the same as for radioactive epinephrine.

Entry of so relatively small a molecule as epinephrine into the ultrafiltrate more slowly than water was consistent with the behaviour of urea, glucose and sucrose<sup>6,7</sup>. No evidence existed for adsorption of the catecholamines on a blood protein<sup>8</sup>. The amount of epinephrine added to each ml. of plasma,  $3 \times 10^{-3} \mu\text{g}$ , was within the range of possible physiological concentrations<sup>9</sup>. In previous investigations<sup>4,10</sup>, the cells were thoroughly washed with Tyrode's solution, and large amounts of a catecholamine were added. The values for  $C_e/C_p$  found after 30 min of incubation were much lower than those in the present study. Active transport may therefore account for the rapid penetration of small amounts of the catecholamines into erythrocytes. Diffusion is the process for larger amounts<sup>10</sup>.

Rapid entry into erythrocytes was consistent with some known aspects of catecholamine behaviour *in vivo* and *in vitro*<sup>11</sup>. In the cat, 90 per cent of an aortic infusion of epinephrine disappeared without physiological effects before reaching the venous circulation<sup>12</sup>. Appreciable amounts of injected epinephrine remained unchanged in the whole mouse after 3 h<sup>13</sup>. In the past, the catecholamine levels within erythrocytes were not determined<sup>9,13,14</sup>. In future studies, this intracellular concentration might be an important variable for study under basal conditions and during stress.

### Intravenous Infusion of Vasopressin to increase the Sensitivity of its Assay in the Water-Ethanol Loaded Rat

THE work of Heller and Stule<sup>1</sup> has been followed by several reports of methods designed to increase the sensitivity of the rat for the assay of vasopressin. In many of these reports the greater sensitivity has been attributed to a more careful operative technique, which may reduce the basal level of endogenous vasopressin secretion by the rat<sup>2,3</sup>. Czaczkes *et al.*<sup>2</sup>, confirming the earlier work<sup>1</sup>, suggested using pre-operated rats in order to avoid surgical trauma on the day of assay, but Jones and Lee<sup>4</sup> did not find the pre-operated rat to be any more sensitive. It seemed desirable therefore to establish whether a high basal level of vasopressin would, in fact, decrease the response of the rat preparation to vasopressin injections.

Female Wistar rats (140–200 g body weight) were water loaded and infused at 0.1 ml./min with hypotonic glucose-saline as previously described<sup>5</sup>. The volume and conductivity of the urine were recorded and the response

to three or four standard doses (2.5–20  $\mu\text{U}$ ) of arginine vasopressin (Sandoz) determined. Arginine vasopressin was added to the infusion in order to reduce the urine flow by about half (0.5  $\mu\text{U}/\text{min}$  was usually required). The response to vasopressin was determined and again after stopping the vasopressin infusion.

Table 1. DOSE OF ARGININE VASOPRESSIN (IN MICRO-UNITS) REQUIRED TO REDUCE THE URINE FLOW BY 25 PER CENT DURING A CONTROL PERIOD AND DURING AN INTRAVENOUS INFUSION CONTAINING VASOPRESSIN (0.5–3  $\mu\text{U}/\text{MIN}$ )

Median 8 $\mu\text{U}$	Median 3.5 $\mu\text{U}$

Table 1 shows that in each of the sixteen experiments the response to a small dose of vasopressin was enhanced by the infusion although larger doses were usually unaffected (Fig. 1). The increased sensitivity permitted the detection of smaller doses of vasopressin; thus 0.5  $\mu\text{U}$  gave a definite response. We noticed that the effects of small doses became greatly prolonged and closely resembled the records published by Tata and Gauer<sup>6</sup>, who claim to have developed an improved assay. Thus the greater sensitivity in their experiments may have been due to a relatively high basal secretion of vasopressin by the neurohypophysis. The prolonged nature of the response and the tendency of the urine flow to become progressively smaller make a background infusion unsuitable for the routine assay of large doses of vasopressin. Such an infusion should, however, prove useful for the detection and assay of vasopressin at physiological levels in the plasma, but only at the cost of a corresponding reduction in specificity and reproducibility. We are in agreement with earlier workers who found the rat to be most sensitive immediately after completion of the surgical procedure, indicating that endogenous secretion of vasopressin is probably enhancing the response to exogenous hormone.

Fig. 1. Effect of an intravenous infusion of arginine vasopressin (1  $\mu\text{U}/\text{min}$ ) on the change of urine volume produced by the intravenous injection of vasopressin. The closed circles are from the control period and the open circles from the period of infusion.

It may seem surprising that the response to vasopressin is enhanced by a background infusion, whereas the effect of oxytocin is reduced<sup>7</sup>. This may be due to the difference in the site of action of the two hormones. Oxytocin acts at the protoplasmic surface membrane of the plain muscle cell<sup>8</sup> where a background infusion might be expected to block the oxytocin "receptors". On the other hand, vasopressin is believed to enter the renal cells at their serosal surface and to exert its action within the cell in which it is subsequently inactivated<sup>9</sup>. Consequently, a background infusion, by saturation of these inactivating mechanisms, would be expected to increase the effect of injections of the hormone.

## MICROBIOLOGY

### Diaminopimelic Acid in the Mu Particles of *Paramecium aurelia*

Mu particles, found in the cytoplasm of *Paramecium aurelia*, stock 540, syngen 1, are responsible for the mate killing effect of this stock on other syngen 1 stocks after conjugation with them<sup>1</sup>. The particles are visible in the phase contrast microscope as rods 2–5  $\mu$   $\times$  10–5  $\mu$  in size, and several thousand may be present in the cytoplasm of a single animal. Beale and Jurand<sup>2</sup> carried out a cytochemical and electron microscope study of these particles and suggested that they were probably bacterial in nature. Van Wagtenonk, Clark and Godoy<sup>3</sup> succeeded in growing the lambda particle of stock 299 (syngen 4) in a complex medium outside the host cell, thus clearly showing that this particle was a symbiont inside the *Paramecium*. It will be shown here that the mu particle is a bacterium in a similar situation, because the analysis of isolated particles has shown the presence of  $\alpha$ - $\epsilon$ -diaminopimelic acid (DAP), and possibly of muramic acid; these are compounds typical of the bacterial cell wall<sup>4</sup>.

Mu particles were isolated from *P. aurelia* stock 540 by a method which involved fractionation of homogenates in a column of cellulose<sup>5</sup>, followed by density gradient centrifugation in a 10–40 per cent gradient of 'Ficoll'. The final preparation contained more than 95 per cent mu particles by phase contrast microscopy, and was contaminated with a small number of mitochondria and other small cell particulates. The number of viable *Aerobacter aerogenes*, the *Paramecium* food, was 0.1 per cent or less. The yield of mu particles was about 1 mg dry weight from 20 mg dry weight of cells. Control preparations from other syngen 1 stocks lacking mu particles gave preparations which contained no mu particles, although they did contain mitochondria, cell particulates and *A. aerogenes* in about the same quantities as the preparations of mu particles. Yield in control preparations was about 1 mg dry weight material from 500 mg dry weight cells. The preparation method will be described in detail later.

Preparations were analysed by paper chromatography and the 'Technicon' amino-acid analyser. Mu particles (2–4 mg) were hydrolysed in 1 ml. 5 normal hydrochloric acid in a sealed tube at 106° for 14 h. After opening the tube, any debris was centrifuged off, and the supernatant was dried *in vacuo* using an infra-red lamp. The residue was washed and dried three times with distilled water, and the final residue was dissolved in 0.05 ml. water (for paper chromatography) or 0.8 ml. water (for amino-acid analysis). Control preparations were treated in the same way, except that no more than 1 mg of material was hydrolysed, because more was not obtained in any preparation.

Paper chromatograms were on 'Whatman No. 3MM' paper, using phenol ammonia in hydrocyanic acid in the first dimension, and *N*-butanol-acetic acid-water (4 : 1 : 5) in the second. Load was equivalent to 1.5–2 mg dry weight of mu. Chromatograms were dipped in 0.25 per cent ninhydrin in 9 : 1 acetone water and heated at 105° for 10 min.

For analysis in the 'Technicon' amino-acid analyser, samples were made 0.5 normal in hydrochloric acid, 0.2  $\mu$ molar norleucine was added, and the final volume was made to 1 ml. The hydrolysate was kept at 100° for 30 min before application. Elution was with a gradient of pH 2.875–5.0, 0.02–0.6 molar sodium ions, as sodium citrate.

Fig. 1 is a photograph of a mu hydrolysate chromatogram, which shows that mu contains at least eighteen amino-acids; chromatograms of control material from *Paramecium* lacking mu showed only 8–10 spots, all feeble, and the number and appearance were variable, unlike those from mu. The small spot arrowed was found reproducibly in mu hydrolysates but never in control preparations; it has an  $R_F$  of 0.18 in phenol, and an  $R_{gy}$  in butanol-acetic acid-water of 0.22, values similar to those reported by Work and Dewey<sup>6</sup> for diaminopimelic acid. It was possible that this spot was caused by ethanolamine-*o*-phosphoric acid, or an oxidation product of cystine, but analysis in the amino-acid analyser showed that a small peak appeared immediately before isoleucine in the elution pattern; this position is that given by Hamilton<sup>7</sup> for diaminopimelic acid, and corresponded with the elution position of authentic diaminopimelic acid. This peak was not found in the elution patterns of control preparations, which showed only twelve amino-acid constituents compared with the nineteen found in mu preparations.

$\gamma$ -Aminobutyric acid was also present in mu preparations but not in control preparations; according to Work

Fig. 1. Chromatogram of a hydrolysate of mu particles, stained with ninhydrin; the diaminopimelic acid spot is arrowed (lower left), and the two hexosamine spots are also arrowed (upper centre). Directions of solvents were as indicated, and the origin was at the lower left-hand corner.

and Dewey<sup>6</sup> this amino-acid is found in many bacteria but is rare in other organisms.

The amount of diaminopimelic acid present was 0.32  $\mu$ M/100 mg, or about 0.07 per cent of dry weight, a value in the range given by Work and Dewey<sup>6</sup>, who in an extensive survey of 118 micro-organisms found diaminopimelic acid in almost all bacteria, but not in yeasts or other fungi, protozoa or plant viruses. It was absent from *Tetrahymena pyriformis*, a close relative of *P. aurelia*. Salton<sup>4</sup> states that the presence of diaminopimelic acid is a distinguishing feature of bacteria and blue green algae, as it is found in the cell wall glycosaminopeptide but in no other cell components.

Attempts were also made to detect the other typical cell wall component of bacteria, muramic acid. While there were usually two hexosamine spots on chromatograms (Fig. 1), and one of these could be identified as glucosamine, the other could not be identified with any certainty as muramic acid, because the ninhydrin and Elson-Morgan reactions were weak and the position of the muramic acid peak in the amino-acid analyser was obscured by the much larger peak of glutamic acid, because of the gradient used for elution; however, there was a small shoulder present on this peak, so it is possible that muramic acid was present.

It may be concluded that the mu particle is a bacterium which has established itself symbiotically in the *Paramecium* cytoplasm, like the lambda particle of stock 299. Further work will aim at investigating biosynthetic capacity in the mu particle, to try to gain an insight into the relationship of protozoan and particle.

I thank Dr H. Kaeser for the use of the amino-acid analyser, Miss M. Richardson for help in interpreting the results, and Professor G. H. Beale for advice.

### Orthorhombic Sulphur formed by Photosynthetic Sulphur Bacteria

THE formation of large mineral deposits of elementary sulphur, for example in Sicily, France, Texas and Louisiana, has often been attributed to microbial processes<sup>1-3</sup>. The similarity of stable sulphur isotope ratios in various sulphur bearing minerals<sup>4-8</sup> to fractionation rates obtained in laboratory bacterial cultures<sup>9-12</sup> gives strong support to the biogenic origin of sulphur deposits.

Elementary sulphur is continuously formed by bacterial action, for example in Cyrenaican lakes near El Agheila<sup>13</sup> and in the Wadi Natrûn, Egypt<sup>14</sup>, typical environments ecologically classified as "sulphureta". In a sulphuretum, primarily, sulphate is reduced to sulphide by sulphate-reducing bacteria of the genus *Desulfovibrio*. The sulphide is then oxidized to elementary sulphur either by photolithotrophic *Thiorhodaceae* and *Chlorobacteriaceae* or by chemolithotrophic *Thiobacteriaceae* or atmospheric oxygen. The elementary sulphur is formed as globules inside the cells of the *Thiorhodaceae* and the large colourless sulphur

bacteria (*Beggiatoaceae*, and in part, *Thiobacteriaceae*), but it is formed outside the cells of the *Chlorobacteriaceae* and *Thiobacillus thio-parus*. Whereas *Thiorhodaceae* and *Chlorobacteriaceae* use reduced sulphur compounds as the hydrogen donor for their anaerobic photosynthesis<sup>15</sup>, thiobacilli obtain all their energy from the oxidation of reduced sulphur compounds, in which molecular oxygen is involved<sup>16,17</sup>. The chemolithotrophic nature of *Beggiatoa* and related forms is doubtful according to recent findings<sup>18-20</sup>. The formation of sulphur globules from sulphide in these species could be just a removal reaction of poisonous hydrogen peroxide which is produced during cell metabolism<sup>21</sup>.

Microscopically, the accumulated sulphur seems to be almost identical among these different metabolic types<sup>22</sup>. The sulphur globules have a high index of refraction<sup>23</sup> and some authors have found them to be birefringent in polarized light<sup>24,25</sup>. As we have seen the globules inside the cells of *Thiocystis* (Fig. 1), we suggest that the interference colours observed in polarized light are not caused by the crystal structure of the sulphur but by the spherical form of the tiny globules in the same way that very small air bubbles exhibit interference colours along their boundaries.

In our investigation, by X-ray diffraction, of the nature of the sulphur formed by purple and green sulphur bacteria (*Thiorhodaceae* and *Chlorobacteriaceae*) we used *Thiocystis violacea* strain 8311, *Chromatium* strain 8111, and *Chlorobium* strain 8430. The strains were isolated from salt water environments using the method of Pfennig<sup>26</sup> and grown in screw-cap bottles using Pfennig's nutrient solution plus 3 per cent sodium chloride at 23° C in continuous illumination of 1,000 lux, provided by a 60 W tungsten lamp. To obtain the sulphur globules, the cells were supplied with freshly prepared and neutralized sterile Na<sub>2</sub>S·9H<sub>2</sub>O solution to a final concentration of 0.05 per cent. After illumination with 2,000 lux, that is, light saturation<sup>27</sup>, for about 30 min the cells had transformed the sulphide into sulphur, which was shown by sulphide analysis of the supernatant<sup>27</sup>. The extracellular sulphur globules of the green bacteria were obtained by low speed centrifugation at 800g. The intracellular globules of *Thiocystis* were recovered by washing the cells twice with sterile filtered seawater and resuspending them in double distilled water; this caused the disruption of the cells by osmotic shock<sup>25</sup>. The sulphur was separated from the other cell constituents by centrifugation at 800g. After washing the sulphur thus obtained from green and purple bacteria with double distilled water, we dried the samples over silica gel for 12 h. All steps were carried out at room temperature to avoid modification of the

Fig. 1. *Thiocystis violacea*, living cells ( $\times c. 1,450$ ) crossed polars.

Fig. 2. X-ray diffractometer traces of sulphur samples. Nickel-filtered copper  $K\alpha$  radiation was used with  $\lambda = 1.5418 \text{ \AA}$ , 40 kVp., 40 m.amp.,  $1^\circ$  divergence slit, 0.006 in. receiving slit,  $1^\circ$  scatter slit,  $2^\circ/\text{min}$  scanning speed, time constant 2 sec, scale in c.p.s. as shown. (A) Reagent grade sulphur, orthorhombic structure, powder packed in aluminium holder, 33 mm sample length. (B) Intracellular sulphur from *Thiocystis* mounted on collodion film, 44 mm sample length. (C) Extracellular sulphur from *Chlorobium* mounted on collodion film, 33 mm sample length. (D) Intracellular sulphur and cell material of *Chromatium* freeze dried on collodion film, 33 mm sample length.

sulphur. The powdered samples were mounted on collodion films<sup>28</sup> and subjected to X-ray diffraction. Fig. 2 shows these diffraction patterns compared with that of reagent grade sulphur. All the patterns give diffraction lines that agree with those of orthorhombic sulphur given in the ASTM powder diffraction file<sup>29</sup>. Some additional weak diffraction maxima are probably the result of unidentified organic material associated with the preparations of sulphur bacteria.

Interference from the diffraction peaks of sodium chloride and other nutrient salts in the medium and from a broad diffraction maximum caused by water defeated several attempts to obtain a useful diffraction pattern of the sulphur still inside whole cells. To avoid the interference of the salinity, the *Chromatium* strain was trained to grow at least very slowly in non-saline medium. The measurement of these cells was also completely inhibited by the presence of water in the cell smear. Ultrasonic treatment of the suspension for 10 min, breaking up the cells and releasing the sulphur into the suspending water, did not have any effect on the diffraction pattern. Freeze drying of the same sample, mounted between collodion pellicles and containing the sulphur as well as the broken cell material, finally showed a small peak indicating the presence of orthorhombic sulphur (Fig. 2D). Considering that about 85 per cent of the dry weight was not sulphur but amorphous organic material, this result seems reasonable.

While purple sulphur bacteria were discovered in 1838 by Ehrenberg<sup>30</sup>, and *Beggiatoa* by Trevisan<sup>31</sup>, their globules were identified as sulphur about 30 yr later by Cramer and Cohn<sup>32</sup>, who showed that the spherical cell inclusions were soluble in carbon disulphide. Winogradsky<sup>33</sup> stated that living cells would always contain globules of amorphous sulphur, while in dead cells crystals would become visible. Sulphur droplets obtained by chemical decomposition of polysulphide solutions were found to appear identical with those inside the cells of *Beggiatoa*<sup>34</sup>. Von Deines postulated that the globules excreted by *Thiobacillus thioautotrophicus* were highly sulphurized polysulphides<sup>35</sup>, but Starkey<sup>22</sup> showed by a

careful analytical investigation that the evidence for this postulate was insufficient. He again confirmed that the globules were sulphur. La Rivière<sup>22</sup> was the first to approach the problem by use of X-ray diffraction, investigating the sulphur of *Thiovulum majus*, a large colourless sulphur bacterium. He obtained the sulphur by osmotic shock of the cells and subsequent low speed centrifugation and found an X-ray diffraction pattern closely resembling that of orthorhombic sulphur.

Despite the different metabolic roles of sulphur in colourless and in photosynthetic sulphur bacteria, we found that the sulphur formed by the latter is also of orthorhombic structure, thus confirming Starkey's<sup>22</sup> statement that "there is no evidence that the globules produced by the larger colourless sulphur bacteria, by the purple (and green) bacteria, or by *Thiobacillus thioautotrophicus* differ chemically".

### Phenoloxidase of *Mycobacterium leprae*

INVESTIGATIONS of the metabolism of *Mycobacterium leprae*<sup>1</sup> have revealed a few of the metabolic characteristics of this micro-organism. Concentrates of *M. leprae* prepared from lepromatous material actively oxidized 3,4-dihydroxyphenylalanine (DOPA) to pigmented products, *in vitro*<sup>2</sup>.

Among several strains of mycobacteria tested (including *M. tuberculosis*, *M. lepraemurium*, and alleged *M. leprae* cultures), only the leprosy bacilli obtained from infected tissues oxidized DOPA; and this specific metabolic activity has been proposed as an identification test for *M. leprae*<sup>3</sup>.

All efforts, extending for nearly a century, to cultivate the causative agent of leprosy in inert culture media have so far ended in failure, none of the numerous claims of success having been confirmed by subsequent work. In consequence, any investigation on the metabolism of *M. leprae* is dependent on limited amounts of infected human tissues available, and only those techniques applicable to small quantities of material could be used. Concentrates of *M. leprae* used in the present investigation were directly separated from lepromatous material. The method used and the purity of the preparation obtained have been reported earlier<sup>2,4</sup>. Because melanocytes in the human skin contain phenolase<sup>5</sup>, it would be useful to investigate if the DOPA oxidase of *M. leprae* is in any way distinguishable from the mammalian enzyme. This enzyme is present in a highly concentrated form in mammalian melanomas. Mammalian phenolase has a limited substrate specificity, and oxidizes tyrosine and DOPA to melanin, L-DOPA being oxidized at a much faster rate than D-DOPA (ref. 6). Diphenols like catechol and catecholamines are not oxidized to any significant degree. The amino group of the tyrosine derivatives must be unsubstituted for activity of the mammalian enzyme<sup>7</sup>. Plant phenolase, on the other hand, has a wide substrate specificity<sup>8</sup>.

This communication reports results on oxidation of D- and L-DOPA and catechol by *M. leprae*. Oxidation of catecholamines by the leprosy bacilli has been reported already<sup>3</sup>. The organisms were separated from infected spleen of a case of lepromatous leprosy removed after death. Cultures of the spleen remained negative, precluding any contamination. Normal human spleen by itself did not contain phenolase<sup>3</sup>. The suspension of bacilli (2 mg protein) was incubated with the substrates at 37° C, pH 6.8, volume 3 ml. (see Table 1 for details). After incubation, the reaction mixture was centrifuged for 45 min at 15,000g and the spectrum of the supernatant was measured in a 'Beckman DU' spectrophotometer. This method was used because the oxidation products of DOPA are well characterized by their absorption spectra<sup>9</sup> and it is sensitive enough for the small amounts of material available. Indole-5,6-quinone was formed by oxidation of DOPA and absorbed maximally at 540 mμ, while o-benzoquinone, produced from catechol, showed a broad peak in the region 520–560 mμ. The results are presented in Table 1. Each substance was tested at least three times; the values given are for typical experiments, and have been corrected for any autooxidation of the substrates and absorbance caused by the bacilli. Heating at 100° C for 15–20 min inactivated the bacilli.

Table 1. PHENOLOXIDASE OF *Mycobacterium leprae*

Substrate	(molar)	Time (min)	Increase in absorbance (540 mμ)
L-DOPA	$3 \times 10^{-2}$	90	0.170
D-DOPA	$3 \times 10^{-2}$	90	0.187
Catechol	$6 \times 10^{-2}$	60	0.143

The results indicate that in the range of substrates oxidized, phenoloxidase of *M. leprae* resembles more closely the enzyme from plant sources than that of mammalian origin. *M. leprae* oxidizes D-DOPA at the same rate as L-DOPA, and also catechol and catecholamines. In the case of melanomas, utilization of D-DOPA is rather low and catechol or catecholamines are not oxidized. Because phenolase of *M. leprae* is different from the mammalian enzyme, the activity of the bacilli could not be caused by adsorption of host tissue enzymes. It is known that phenolase specificity becomes narrower with rise in the phylogenetic scale<sup>9</sup>. It is interesting to point

out that taxonomically *M. leprae* comes under class Schizomycetes, to which fungi also belong. Fungi are known to be rich in phenolase<sup>10</sup>. Because phenolase might serve as an alternative mechanism for the oxidation of various substrates by *M. leprae* through the quinones formed in the reaction<sup>2</sup>, this finding offers possibilities for a rational approach to cultivation of the bacillus (providing utilizable substrates) as well as chemotherapy of the disease (use of selective inhibitors).

This investigation was supported by the US Public Health Service. I thank Dr W. F. Kirchheimer for encouragement and Dr R. E. Mansfield for supplying autopsy specimens used in this study.

## Susceptibility of a New World Monkey to *Plasmodium falciparum* from Man

LABORATORY investigations of the biological and biochemical characteristics of malarial parasites from man have been hampered by the lack of infected patients and of susceptible laboratory animals. In order to prolong the cultivation of plasmodial species *in vitro*<sup>1</sup>, we sought a supply of blood infected with *Plasmodium falciparum* and *P. vivax*. Apart from nine cases of human malaria and two samples of frozen human infected blood, no steady supply for our experiments was available in the Bay area of California. Storing or freezing the blood causes the parasite to change before the experiments are begun.

The report by Porter and Young<sup>2</sup> on the susceptibility of the New World monkey, *Aotus trivirgatus*, to *Plasmodium vivax* offered a solution of this problem. Previous attempts to infect Old and New World non-human primates<sup>2-4</sup> showed that the splenectomized chimpanzee (*Pan satyrus*) was susceptible to *P. vivax* and *P. falciparum* and that the howler monkey, *Alouatta* spp., was susceptible to *P. falciparum*. More recently, splenectomized gibbons, *Hylobates lar*, have been shown to be susceptible to *P. falciparum*<sup>5,6</sup>. Chimpanzees and gibbons are costly and difficult to feed and house, so we obtained instead night monkeys, *Aotus trivirgatus*, from a local dealer. The animals were examined for spontaneous infections of blood parasites before and after splenectomy. One splenectomized *Aotus* was inoculated intraperitoneally with blood containing  $105 \times 10^6$  *P. vivax* taken from a soldier who had returned from Vietnam. After a 24 day pre-patent period, we confirmed the report of Porter and Young<sup>2</sup> about susceptibility. The maximum parasite count in this animal was 76,200/mm<sup>3</sup> on the seventeenth day of the patent period.

On October 25, 1966, a female patient, who had been admitted to the Palo Alto-Stanford Hospital five days before, was diagnosed as having an acute infection with *P. falciparum* (Fig. 1). The patient was semi-comatose when seen and the parasitaemia was 125,000 parasites/mm<sup>3</sup> of blood. The infection was contracted in Uganda. The severity of the infection was also shown

Fig. 12. The course of infection of *Plasmodium falciparum* in a New World monkey, *Aotus trivirgatus*.

by the presence of asexual stages of parasites in the circulating blood (Figs. 2 and 3).

Blood obtained from this patient was heparinized, and 10.2 ml. containing  $1.29 \times 10^9$  parasites was inoculated intraperitoneally into a splenectomized *Aotus*. After a pre-patent period of 54 days, a few rings and immature gametocytes were found on thick films. The later course of infection is shown in Fig. 12. Asexual stages, immature and eventually mature gametocytes (Figs. 6–11) appeared in the circulating blood, and the infection at its peak reached a parasitaemia of  $180,000/\text{mm}^3$  (5.25 per cent).

1.8 ml. of blood from this animal (containing  $7.02 \times 10^7$  parasites) was inoculated intraperitoneally into another *Aotus*. After a 19 day pre-patent period, this animal gave a positive reaction and 24 per cent of the erythrocytes were parasitized on the nineteenth day of the patent period. The parasites showed no preference for reticulo-cyte invasion. The animal died on the thirty-first day of the patent period because it was bled heavily for passage and for *in vitro* studies to be reported elsewhere.

The first infected animal and other animals later infected at no time showed detectable gross clinical symptoms. The strain of parasites in the donor patient was certainly highly virulent, but additional infections and autopsies are needed to determine pathogenesis for *Aotus*.

We are now able to maintain the infection by passage to splenectomized *Aotus*. An infection in an intact recipient animal has also become positive, indicating adaptation to this host. In the passage animals, asexual stages of the parasites continue to occur in the peripheral blood together with immature and mature gametocytes. We plan to study the gametocytes to determine their maturity and infectivity for anopheline mosquitoes.

In order to have different strains of *P. falciparum* available for *in vitro* culture and biochemical study, we are trying to isolate a chloroquine-resistant strain of *P. falciparum* in *Aotus trivirgatus*.

Finally, we should point out that infected animals must be kept in adequately screened cages to prevent access by anopheline mosquitoes to a blood meal containing a high percentage of gametocytes. Also, *Aotus* is scarce and apparently difficult to keep in captivity. Mature animals are relatively small, weighing about 0.5–0.8 kg; they must be housed at not less than 80° F; and they

must be adapted to available but acceptable food. Perhaps primate centres can be approached to study and propagate these animals for malaria experiments and for the study of other aetiological agents of disease in man, such as infectious hepatitis, because the susceptibility of *A. trivirgatus* to human malaria suggests that its erythrocytes and plasma are similar to the constituents of human blood.

### Inhibition of Growth of Subtilis Phage SP-50 by Histones

BUKRINSKAYA *et al.*<sup>1</sup> demonstrated the inhibitory effect of histones on the growth of fowl plague virus—one of the viruses which contains RNA. Synthesis of RNA and viral haemagglutinin in infected chicken fibroblast cells were inhibited by calf thymus histones. Recently, it was found that when histones were added they reduced the multiplication of Semliki forest virus—another virus containing RNA, and vaccinia virus, which contains DNA<sup>2,3</sup>. In all these studies chicken fibroblast cells were used. The present investigation was carried out to examine the effect of histones on the growth of subtilis phage SP-50 in bacterial cells thought to be free of histones.

The bacterium used in the experiments was *B. subtilis*, r168. The phage was subtilis phage SP-50 which contains DNA. It was originally isolated by Trautner<sup>4</sup>. Both the bacteria and the phage were kindly provided by Dr A. Trautner. The histones used were total histones from calf thymus, prepared by acid extraction.

Bacteria were grown to a density of about  $2 \times 10^8$  bacteria/ml. in a minimal medium containing salts, yeast extract, asparagin and tryptophan. After centrifugation of the bacteria the adsorption of the phage was allowed to take place for 5 min at 37° C in a medium containing sodium chloride, yeast extract and tryptone. The bacteria were then centrifuged again, resuspended in a tenth of the original volume in a solution containing sodium chloride, sodium citrate and 200 g sucrose/l., and transformed into protoplasts by treatment with 100 µg/ml. of lysozyme for 30 min at 25° C. Finally, the suspension of infected protoplasts was diluted to a thousandth in the minimal medium containing 200 g sucrose/l. and raised in temperature to 28° C.

The method used to determine the incorporation of radioactive phosphorus into RNA during phage synthesis was as follows. About 1 mc. of radioactive phosphorus was added to 500 ml. of infected protoplasts. After incubation for 30 min at 28° C the suspension was passed through a 'Millipore' filter to retain the protoplasts, and treated first with 5 per cent perchloric acid, and then with ethanol. Afterwards the filter was dissolved in acetone. The precipitate was then centrifuged, the RNA extracted with 17 per cent perchloric acid overnight at 4° C and the radioactivity determined.

When histones were added to a culture of bacteria infected with SP-50, no decrease in the production of

phage was observed. The bacterial cell wall probably inhibited the entry of histones into the cell. Brenner *et al.*<sup>5</sup> had previously succeeded in growing phages in protoplasts, and therefore we tried this with subtilis phage SP-50. Fig. 1 is the growth curve of subtilis phage SP-50 in protoplasts. The infectious phage increased by a factor of about thirty. Intact bacteria gave somewhat higher yields than protoplasts.

Fig. 2 shows the effect of different concentrations of histones on the growth of subtilis phage. Small amounts of histones were able to suppress the growth of the phage, but more histones were needed to increase the concentration of protoplasts. Addition of histones was more effective if it was done early in the latent period (Fig. 3). Suppression of the growth of phage by dilution with sucroseless medium (causing disruption of the protoplasts) remained approximately the same throughout the latent period. It is therefore unlikely that the

Fig. 1. Growth of subtilis phage SP-50 in protoplasts. Bacteria were infected at a multiplicity of about 0.1, transformed into protoplasts, incubated at 28° C and samples were removed at different times.

Fig. 2. Effect of different concentrations of histones on the growth of subtilis phage SP-50. Multiplicity of infection was about 1.5. The protoplasts were incubated for 120 min with different concentrations of histones.

Fig. 3. Effect of histones at different times after infection. Multiplicity of infection was about 0.1. The protoplasts were incubated for 120 min. Histones were added at different times during the incubation.

increased resistance to histones was caused by partial repair of the protoplasts during incubation.

Direct observation under the microscope shows that small amounts of histones, which have an inhibiting effect on the multiplication of the phage, do not disrupt the protoplasts to any noticeable extent. It is probable that histones do not act simply by disrupting the protoplasts. Experiments by Huang *et al.*<sup>6</sup>, Allfrey *et al.*<sup>7</sup> and others have demonstrated that histones block RNA synthesis. To determine whether this is the mechanism by which histones inhibit the synthesis of the new phage, I studied the incorporation of radioactive phosphorus into RNA during phage growth both in the presence and in the absence of histones. The results are presented in Table 1. In all three experiments

Table 1. EFFECT OF HISTONES ON THE INCORPORATION OF RADIOACTIVE PHOSPHORUS INTO RNA DURING PHAGE SYNTHESIS

Experiment	Acid and ethanol soluble fraction 10 <sup>3</sup> counts/ml.	RNA 10 <sup>3</sup> c.p.s.	Histone µg/ml.
1	1,120	24	—
	844	6	1.25
2	32	4	—
	33	1	1.25
3	770	37	—
	721	17	1.25

Bacteria were infected at a multiplicity of about 2.0 and transformed into protoplasts. About 1 µc. of radioactive phosphorus was added to 500 ml. of the suspension. The protoplasts were then incubated for 30 min at 28° C with and without histones, the RNA was extracted and the radioactivity determined.

the radioactivity in the RNA extracted from samples incubated without histones was between three and four times greater than that in samples incubated with histones. This difference is not great enough to account for all the suppression of the phage growth caused by histones. Possibly the samples which contained histones showed excessively high radioactivity because of incomplete removal of contaminating radioactive phosphorus by the treatment with perchloric acid and ethanol. The results support the idea that histones inhibit the growth of subtilis phage SP-50 by preventing RNA synthesis. This would mean that extraneous histones act in bacterial cells in the same way as in animal cells. It is possible that the increase in the resistance to histones at the later stages of the latent period is because in that time most of the phage specific RNAs have already been synthesized.

I thank Mrs Pirkko Kumpulainen and Miss Heli Puumala for their invaluable technical assistance. This

investigation was aided by grants from the Sigrid Juselius Foundation and the Finnish National Research Council for Medical Sciences.

## PATHOLOGY

### Infectivity of *Trypanosoma rhodesiense* to Tsetse Flies fed through Animal Membranes

THE trypanosomes belonging to the *Trypanosoma brucei* group (agents of sleeping sickness and nagana) exist in the blood of the host in three main morphological forms—long thin, intermediate and short stumpy. When these are taken up by the tsetse fly they undergo developmental changes, namely trypanosome, crithridial and metacyclic forms, the last being infective to the vertebrate host. There is controversy about which forms are infective to the fly, the long thin, the short stumpy or both.

It is well established that the blood forms of the trypanosomes retain their viability as well as other biological characteristics after long periods of storage at  $-79^{\circ}\text{C}$  (refs. 1 and 2). Feeding through membranes has been used for the regular maintenance of tsetse flies in the laboratory<sup>3</sup>, and for the collection of metacyclic trypanosomes from infected flies<sup>4</sup>. An unsuccessful attempt to infect *Glossina pallidipes* with preserved *Trypanosoma brucei* group trypanosomes was made by Cunningham<sup>5</sup>, who suggested that the failure was caused by the absence of short stumpy forms from the suspension used.

During a study on the infectivity of the two main morphological forms of these trypanosomes to tsetse flies, a batch of twenty-three *G. palpalis* were given an infective blood meal which contained only the long thin forms of *T. rhodesiense*, through a fresh mouse skin membrane. The morphology of the trypanosomes was determined by the method described by Ormerod *et al.*<sup>6</sup>. One of the flies later extruded trypanosomes in its salivary secretion, and transmitted the infection to a guinea-pig before it died (42 days after). This suggests that, under certain conditions, both morphological forms of these trypanosomes may become established in the fly<sup>7-10</sup>, contrary to the results of several workers<sup>11-13</sup>. The blood of the guinea-pig, containing both long thin and short stumpy trypanosomes, was frozen at  $-79^{\circ}\text{C}$  in ampoules.

After 14 months the contents of one ampoule were fed to nine newly emerged *G. austeni* through a fresh mouse skin membrane. Three flies died within 10 days and were not examined. All other flies were dissected as soon as possible after death. One infected fly was detected on the twenty-sixth day; however, when the flagellates obtained were subsequently inoculated into a rat, no infection occurred.

After 16 months' storage at  $-79^{\circ}\text{C}$ , the contents of another ampoule were similarly fed to twenty-two *G. austeni*, of which eleven survived to the tenth day. Two flies which died on the fourteenth day contained active trypanosomes which produced an infection in a mouse. Five other flies dissected between the nineteenth and

twenty-eighth days contained active trypanosomes, but these did not infect test animals.

It is therefore concluded that tsetse flies may be infected with preserved *T. brucei* group trypanosomes by feeding through membranes. The successful infection of a fly from a suspension which contained only long thin trypanosomes indicates that negative results, such as those of Cunningham<sup>5</sup>, would result from some reason other than the absence of short stumpy forms in the blood meal. It is suggested that the technique of membrane feeding, as opposed to that of feeding flies on infected animals, offers more precise conditions for investigation of the factors which influence the infection rate of tsetse flies with these trypanosomes. These investigations should be based on the factors in the trypanosomes; the mammalian host; and the individual tsetse<sup>14</sup>. Other characteristics of the trypanosomes that may be investigated in this way include their infectivity, transmissibility by tsetse, antigenicity and drug resistance. The preservation of metacyclic trypanosomes derived from tsetse flies<sup>4</sup> adds considerably to the possibilities of such studies.

I thank Dr W. E. Ormerod for his guidance, and Dr T. A. M. Nash and Mr T. M. Leach for the supply of tsetse pupae. This work was supported by the Rockefeller Foundation.

### Leaching of Constituents of Chrysotile Asbestos *in vivo*

IN recent years, Wagner<sup>1</sup> and Selikoff *et al.*<sup>2</sup> have shown that a rare tumour, the diffuse mesothelioma of the pleura and peritoneum, is associated with past exposure to asbestos. It appears that the amount of asbestos required to produce these tumours is small and that the latent period is very long. The connexion between exposure to asbestos and the production of mesotheliomas is being studied in a number of laboratories, and the possibility that trace metal constituents or contaminating oils may have a role has been suggested<sup>3</sup>. As yet, little is known about the fate of inhaled asbestos fibres and in particular about their movement out of the lung into other organs. The experiment described here was planned to assess the possibility of using radioactivity, induced in asbestos fibres by neutron irradiation, to trace their translocation in rats after administration by intrapleural injection.

A sample of Rhodesian chrysotile was irradiated in a high flux of thermal neutrons ( $1.5 \times 10^{14}/\text{cm}^2/\text{sec}$ ) for 10 h. After allowing some weeks for the short-lived activity to

decay, the principal  $\gamma$ -emitting constituents were found to be scandium-46, chromium-51, iron-59 and cobalt-60, all of which are produced in  $(n,\gamma)$  reactions on the stable elements. The half-lives and principal  $\gamma$ -ray energies of these nuclides are listed in Table 1, together with the concentrations of the corresponding stable elements in the chrysotile determined by activation analysis (Sandalls, F. J., personal communication).

Table 1. CHARACTERISTICS OF NUCLIDES INDUCED IN CHRYSOTILE

Element	Concentration in chrysotile (p.p.m.)	Radio-nuclide	Half-life	Principal $\gamma$ energies (MeV)	
Scandium	$5 \pm 1$	$^{46}\text{Sc}$	84 days	0.89	1.12
Chromium	$780 \pm 10$	$^{51}\text{Cr}$	28 days	0.323	
Iron	$38,000 \pm 1,000$	$^{59}\text{Fe}$	45 days	1.10	1.29
Cobalt	$77 \pm 2$	$^{60}\text{Co}$	5.27 yr	1.17	1.33

Before administration, the irradiated fibre was suspended in physiological saline and sterilized by  $\gamma$ -irradiation. Two 3 month old rats were anaesthetized and injected intrapleurally<sup>4</sup> with 0.4 ml. of this suspension (equivalent to about 3 mg of asbestos). The injection was in the right axilla at the level of the second nipple. After administration, the rats were housed in metabolic cages of the type described by Howells *et al.*<sup>5</sup> which permit the separate collection of urine and faeces. One animal was killed after 8 and the other after 50 days, after which they were dissected and the principal organs removed for analysis by  $\gamma$ -ray scintillation spectrometry. Care was taken to avoid cross contamination of tissue samples.

The  $\gamma$ -ray scintillation spectra of the asbestos and of samples of tissue and excreta arising during the experiment were measured with a 3 in. diameter  $\times$  3 in. deep thallium activated sodium iodide crystal detector, using a linear amplifying system and multi-channel pulse height analyser. The amounts of each nuclide in the various samples were calculated using a least squares analysis of the  $\gamma$ -ray spectra using standard spectra of the individual components. The analyses were performed by the GASP computer programme devised by Salmon<sup>6</sup> which produces a graphical presentation of the experimental points and the fitted curve. An example of this presentation showing the  $\gamma$ -ray spectrum of irradiated chrysotile and the fitted curve is shown in Fig. 1.

Analysis of the  $\gamma$ -ray spectra of urine samples showed them to contain only chromium-51 and cobalt-60. After 50 days, 19 per cent of the chromium-51 and 57 per cent of the cobalt-60 had been excreted by this route. This

Fig. 1.  $\gamma$ -Ray scintillation spectrum of neutron irradiated chrysotile. —, Fitted curve; ●, experimental points. All energies in KeV.

Fig. 2. Urinary excretion of chromium-51 (▲) and cobalt-60 (●).

shows conclusively that chromium and cobalt are both leached quite rapidly *in vivo* from chrysotile asbestos. The daily excretion rates of these two nuclides are shown in Fig. 2.

All four nuclides were detected in faeces but in comparatively small amounts. Their presence in faeces could be accounted for by small amounts of fibre entering the lung from the pleura and subsequently being transported by the normal ciliary clearance mechanism to the glottis and gastro-intestinal tract.

Small amounts of all four radionuclides were detected in tissue samples. Relatively high levels of iron-59 in both blood and liver indicate that iron is also leached from the asbestos, but to a much smaller extent than either chromium or cobalt. The evidence does not permit any conclusions to be drawn regarding the leaching of scandium.

In both animals, about 90 per cent of the amount of each radionuclide remaining at the time of death was found in the pleural cavity and lungs. Some of the activity was associated with visible plaques on the diaphragm and pleura. The distribution indicates that the translocation of fibres out of the pleural cavity into other organs is a comparatively slow process. The fact that small amounts of all four radionuclides were, however, found in organs outside the chest region suggests that some translocation of fibres does occur although additional evidence possibly supported by autoradiographic studies, will be required to prove this conclusively.

# BOOK REVIEWS

## MEDIAEVAL MINERALOGY

### Book of Minerals

By Albertus Magnus. Translated by Dorothy Wyckoff. Pp. xlii + 309 + 2 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1967.) 84s. net.

ALBERTUS MAGNUS, whose dates are usually given as 1206–1280, was the most learned man of his day, taking all knowledge for his province. He was a Dominican, and famous in his own time not only for his scholarship but for his piety. Even in his lifetime he became the centre of legend. In some quarters his knowledge of alchemy caused him to be regarded as a magician skilled in the black arts; by others he was looked upon as a saint who could perform miracles. As early as 1484, the date of his death (November 15) became officially recognized by the Pope as “Albert’s Day”, and in 1931 he was canonized.

Albert was a scholar through and through, and a devout follower, translator and commentator of the works of Aristotle, the shadow of whose doctrine extended over two millennia, effectively preventing true scientific advance based on observation and experiment. But yet in Albert’s works there are many signs that, almost alone among mediaeval thinkers and writers, he was a shrewd observer of animal and mineral nature. His written treatises cover an enormous range, and even their sheer bulk is sufficiently impressive. The new Cologne edition of his works, for example, is in forty volumes, of which nine comprise his works on natural science. Most of these are based on works of Aristotle, in which case the original text is paraphrased and interwoven with expositions of Albert’s own, or refutations of the opinions of earlier commentators. In the *Book of Minerals*, there was no basic text, which left more scope for development of his own ideas, though his model is still Aristotle, with his doctrine that concrete particulars obtained by direct observation of nature are often confused and difficult to understand and that science should apply itself to analysing these data in order to arrive at the underlying general principles or causes. And for Aristotle, and therefore for Albert, the four causes of minerals come under the headings “Material”, “Efficient”, “Formal” and “Final”.

For the material cause, the composition of minerals, Albert had to juggle with the accepted four “elements”, fire, air, water and earth. On this unpromising basis, Albert divides minerals into three groups—stones, which are mixtures of earth and water; metals, which are made up of sulphur and quicksilver, which are themselves mixtures; and intermediates, which have certain characteristics of both stones and metals.

For the efficient cause, or the processes by which minerals are made, Albert relies on the reactions of exhalations such as “dry smoke”, or sulphur, and “moist vapour” or quicksilver, which are converted by a mineralizing power acting through the instruments of heat and cold. The formal cause is that which determines the nature of the mineral, and this formative power comes to us from the heavens through the influence of the planets and stars. Lastly, the final cause, which is concerned with why a thing exists, is not stressed by Albert, because inanimate mineral matter was not considered by Aristotle or by Albert to have a significant purpose of its own.

With such a scheme as this, an author cannot be expected to produce a work on mineralogy which has a recognizable affinity with any tract written on the same subject in the nineteenth or twentieth century. The sort of qualities of a mineral which we consider to be valuable

indications of its nature and identity—texture, colour, hardness, cleavage, density—are here regarded as “accidental”, not essential, and thus unimportant. Even crude figures for density, for example (and certain Arabs had by this time arrived at quite fair values, using Archimedes’ principle), would have helped us greatly in identifying correctly the species with which Albert deals: but none at all is given.

The first book having dealt with the general properties of stones, the second concerns itself with precious stones and their powers, which, rather curiously, are considered in alphabetical order, from asbeston, admas, absinthus, agathes . . . to zemech (lapis lazuli) and zigrifis (probably fabulous). There is a section (“tractate”) on images and sigils in stones in which Albert shows a curious ignorance of the art of gem-cutting or cameo carving, and accepts so highly finished a work of art as the “Ptolemy” cameo as a product of nature.

The third book concerns “Metals in General”, the fourth book deals with “Individual Metals”, and the fifth book with “Minerals that seem to be intermediate between stones and metals”.

The translation of the *Book of Minerals* itself takes up 250 pages of the present volume, and incorporates ample notes on the text and cross references to, for example, Albert’s possible sources and other comparable works. In addition there are some twenty-five pages of introduction, sketching Albert’s life and the circumstances in which the *Book of Minerals* was written; the book ends with some valuable appendices and an index.

The translator and editor, Dr Dorothy Wyckoff, was until recently professor of geology at Bryn Mawr College, and had spent many years in her study of the *Book of Minerals*. She is to be congratulated on a fine piece of scholarship, which will not only reward and delight students of mediaeval science, but will serve for others who are not familiar with the period as an accurate yet very readable introduction to those strange times, when superstition and learning were intimately mixed, when astrology was indistinguishable from astronomy, alchemy from chemistry, and hearsay from hard fact.

B. W. ANDERSON

## FUNCTION THEORY APPLIED

### New Methods for Solving Elliptic Equations

By I. N. Vekua. Translated from the Russian by D. E. Brown. Translation edited by A. B. Tayler. (North-Holland Series in Applied Mathematics and Mechanics, Vol. 1.) Pp. xii + 385. (Amsterdam: North-Holland Publishing Company; New York: John Wiley and Sons, Inc., 1967.) 100s.

THE original Russian edition of this book appeared in 1948, so that since then a knowledge of the methods used has had time to spread. Vekua himself published a very large number of papers in this field during the 1940’s. Many of these papers related to plane problems in anisotropic elastic media, part of the notable contribution to the mathematical theory of elasticity made in recent years by Soviet scientists; much of Vekua’s work shows the influence of Muskhelishvili. Related material has also been made available in Vekua’s book on generalized analytic functions (1959; with an English translation, published by the Pergamon Press in 1962); this again gave many applications to elasticity.

The familiar simplification of many two-dimensional problems obtained by the use of a complex variable  $z$  can be widely generalized by a transformation  $z = x + iy$ ,  $\bar{z} = x - iy$ , where if  $x$  and  $y$  are restricted to be real,  $\bar{z}$  specializes to the conjugate of  $z$ . The differential operators associated with these variables permit an application of complex function-theory to the general representation of solutions of second order partial differ-

ential equations of elliptic type in two independent variables. The kernels of these operators can be expressed in terms of the Riemann function, dependent on the coefficients in the partial differential equation. As an illustration, the connexion of special cases with the Bessel and Legendre functions is shown. The imposition of boundary value conditions effects a reduction to integral equations: these may be of Fredholm type, but much use is made of singular integral equations involving principal value integrals, a field in which Muskhelishvili's 1946 book (with an English translation in 1953) is a basic reference. Applications are made to vibrations of a membrane, elastic spherical shells and other elasticity problems.

The reader should possess a sound knowledge of the classical theory of functions of a complex variable, and of the basic equations of theoretical elasticity. He will then appreciate the book as another example of the way in which Soviet mathematicians exploit the resources of high-powered analysis in the practical application of mathematical theories.

T. A. A. BROADBENT

## OPERATIONAL CALCULUS

### Introduction to the Operational Calculus

By L. Berg. English translation of the second edition. (North-Holland Series on Applied Mathematics and Mechanics, Vol. 2.) Pp. x+294. (Amsterdam: North-Holland Publishing Company, 1967.) 80s.

OPERATIONAL calculus was developed by Heaviside and used by many of his successors on an intuitive basis. The closest approach to a mathematical theory of the original Heaviside calculus is presented by J. P. Dalton in *Symbolic Operators* in 1954. About fifty years ago it was discovered that Laplace integrals could be used effectively as a substitute for operational calculus, and since then most investigators aiming at precision and mathematical rigour have used Laplace transforms.

Laplace transforms, however, have some shortcomings from the point of view of an applied mathematician. Laplace integrals do not have any obvious physical significance; in order to ensure their convergence, it is necessary to impose certain unnatural growth restrictions on the functions subjected to the transformation; and Laplace transforms involve the values of the functions concerned for all positive values of the variable, while the physical processes to which they are applied depend at any time  $t$  on the past of the system, but not on its future.

About 1950, Jan Mikusinski developed an operational calculus which is free from these blemishes and is mathematically rigorous. Mikusinski's operational calculus is based on the convolution integral

$$\int_0^t f(u)g(t-u)du$$

which is Duhamel's integral and can serve to introduce a species of product in the space of continuous functions of a positive variable. Continuous functions endowed with pointwise addition and convolution as multiplication form an algebraic system to which the usual processes of modern abstract algebra can be applied, and lead not only to an operational calculus but also to a concept of generalized functions including impulse functions. The function which is constant and equal to unity serves as the operator of integration, its reciprocal is Heaviside's operator of differentiation, the unit element of the algebraic system constructed by Mikusinski is the delta function, and so on.

The book being reviewed has grown out of courses of lectures delivered by Berg to students of mathematics, physics and electrical engineering. The author presents both the Laplace transform approach and Mikusinski's

operational calculus, and he describes more briefly a extension of Laplace transforms which relaxes considerably the global integrability conditions. The reader is assumed to be thoroughly familiar with advanced calculus and the elements of complex variable theory, but in other respects the book is self-contained, and includes, for example, a detailed exposition of the concepts and method of abstract algebra needed in the sequel. Before developing Mikusinski's operational calculus, Berg presents the corresponding operational calculus for functions of a discrete variable, that is, for sequences. This is in the nature of a preliminary exercise, and serves to introduce some of the concepts and techniques that will appear in later parts of the book, but the calculus so developed is of interest for its own sake. In the development of operational calculus for functions of a continuous variable the author departs from Mikusinski in that he introduces the modified convolution product

$$fg(t) = \frac{d}{dt} \int_0^t f(u)g(t-u)du$$

in order to achieve certain formal simplifications. The operational calculus so developed is then applied to the solution of ordinary differential equations with constant coefficients, systems of such equations, and to integral equations of the convolution type.

Laplace transforms are also developed and applied to the solution of ordinary linear differential equations with polynomial coefficients, partial differential equations of difference equations, and integral equations of convolution type. Additional material includes asymptotics; an extended concept of Laplace transforms; an operational calculus based on the finite Laplace transformation; operational calculus for functions of two variables; and an operational calculus based on Volterra's theory of compositions and applicable to ordinary linear differential equations with variable coefficients.

The first German edition of this book appeared in 1961 and sold so well that a second corrected and somewhat enlarged edition could be published by 1964. The translation reviewed here is based on this second edition. Problems with answers have been added. A. ERDÉLYI

## DIFFICULT FLUIDS

### Non-Newtonian Flow and Heat Transfer

By A. H. P. Skelland. Pp. xvi+469. (New York and London: John Wiley and Sons, Inc., 1967.) 140s.

THE time is undoubtedly ripe for a general book on non-Newtonian technology. A few years ago the subject was sufficiently new and specialized for original papers to be the appropriate source of basic information, but the body of knowledge and the range of users have grown so fast that a readable guide to the state of knowledge is very welcome. With the exception of Wilkinson's monograph *Non-Newtonian Fluids*, this field has been noticeably lacking in such surveys, and Professor Skelland has done a good service in undertaking the task. The size of the task is perhaps indicated by the length of the bibliographies attached to each chapter. More than four hundred books and papers are quoted, so that this book would provide an excellent start to a literature search.

The author has aimed to make his book useful to a wide range of readers, while keeping engineering applications, rather than analytical detail, to the forefront. The practising engineer who meets an isolated problem in non-Newtonian flow will find here all the information he needs, if it exists yet, although it is not always presented in the most convenient form for immediate use. The undergraduate will appreciate the down to earth approach and the worked and unworked examples, but may be

confused by occasionally woolly arguments and unnecessary changes in nomenclature, both of which, one hopes, will be corrected in a second edition. Finally, the more advanced worker will value the book as a background survey, going to more sophisticated texts in his own specialism. One hopes that the very least result of Skelland's effort will be that future writers of research papers on non-Newtonian flow will refer tyro readers to his work instead of swelling the literature volume with needless repetitions of elementary definitions.

Skelland develops his subject through a logical sequence of sections on fluid classification, determination of properties, laminar and turbulent flow, boundary layers, mixing and heat transfer. Each topic is covered by a well balanced combination of theory and empirical data, and the layout of the chapters has been carefully thought out so as to facilitate extraction of information. The only exception is the section on laminar flow, in which an artificial distinction between fluids with and without yield stress has led to the derivation of generalized correlations being split between three chapters.

A surprising, but welcome, inclusion is a chapter on optimization. This will be appreciated by the pipeline designer for reference, but the development is far more general than the book title would suggest and deserves a wider student readership than is expected for this work. The concept of costing is ill-appreciated by too many engineering students, and Skelland may have established a desirable precedent by emphasizing this point in a book not specifically devoted to design economics.

Although this book is rather expensive for many individual buyers, any organization which might encounter non-Newtonian fluids should regard it as an essential purchase for the library.

JEAN M. DRABBLE

## LOOKING INTO PETROL

### *Petroleum Microbiology*

By J. B. Davis. Pp. xiv + 604 with 208 illustrations and 160 tables. (Amsterdam, London and New York: Elsevier Publishing Company, 1967.) 240s.

THE exploding science of petroleum microbiology has been particularly devoid of good literature. Ernest Beerstecher's *Petroleum Microbiology* of 1954 has become the standard reference for most workers in the field and has done much to promote his original aim, which was the marriage of petroleum engineering and bacteriology. A revision or a new standard text has, however, been long awaited and Dr J. B. Davis has set out to produce the latter but in the Beerstecher mould.

The expansion of Beerstecher reflects Dr Davis's particular interests in the wealth of information on geological factors, prospecting and oil recovery and acknowledges the Russian literature in this field. It is perhaps a sign of the times that the disposal of petroleum waste, which occupies less than a page in Beerstecher, commands forty-two pages in the new text. Not only are conventional activated sludge processes covered in some detail but the account of the successful use of a refinery cooling tower for waste treatment must surely stimulate more venturesome methods. At a time when oil tanker wrecks are an international talking point, it is gratifying to find space devoted to the natural degradation of petroleum by micro-organisms in natural waterways, a fact of life which is sometimes missed by those responsible for beach and sea cleanliness.

Perhaps the greatest advances since Beerstecher have been in the field of biosynthesis from petroleum products, and Dr Davis draws on a variety of sources to indicate current trends in the production of high cost chemicals from such low cost substrates as methane.

In dealing with detrimental aspects of microbial activity he explodes the myth that conditions at the

bottom of fuel storage tanks are anaerobic and advocates a reappraisal of spoilage prevention by careful attention to formulation rather than the indiscriminate use of additives. Dr Davis exposes our rudimentary knowledge of degradation in complex oil formulations, but fails to indicate the wider implications of microbial spoilage in steel and aluminium rolling oils, hydraulic oils and water contaminated lubricating oils.

In assessing the merit of this book there can be little doubt that it will become as much a standard reference as Beerstecher, and probably more so. In a book aiming to bridge conventional subject frontiers, clear, adequate and relevant illustration is particularly important, and it is a pleasure to record that even the photomicrographs, so often hazy squiggles and dots, show recognizable micro-organisms. A few cases of inadequate legend (pages 505 and 535) are minor irritations. Engineers and chemists will find little to enable them to isolate, enumerate and identify micro-organisms. More guidance on this technology would be helpful, because it is fraught with pitfalls for the beginner. A level of knowledge of microbiology is assumed which is probably greater than that of even the interested chemist or engineer. A few pages of basic biology would therefore add to the completeness of the book, and a glossary would ease the task of initiates in this multi-subject discipline.

E. C. HILL

## MICROBES IN THE AIR

### *Airborne Microbes*

Edited by P. H. Gregory and J. L. Monteith. (Seventeenth Symposium of the Society for General Microbiology held at the Imperial College, London, April 1967.) Pp. xii + 385. (London: Cambridge University Press, 1967. Published for the Society for General Microbiology.) 75s. net; \$13.50.

*Airborne Microbes* comprises the contributions to a most successful symposium held by the Society for General Microbiology in London in April 1967. The editors in their preface point out that the sampling measurement and interpretation of airborne microbes have challenged the ingenuity of workers in several disciplines, and a symposium providing a common platform on which progress could be reviewed was both timely and apposite.

In the first section, entitled "Air Movement", F. H. Ludlam, in non-mathematical terms, describes the factors affecting the circulation of air, water and particles over trans-continental distances in the Earth's atmosphere. J. B. Tyldesley discusses the suspension and movement of particles in the "frictional layer of the atmosphere" and on the basis of a computer study presents an analysis of eddy diffusion over a short scale. The flow of illuminated tracer particles in air streams indoors is illustrated with a series of photographs by L. F. Daws, who shows the effects of, for example, external wind, heating and even the occupants of a room.

In the second section, entitled "Air Sampling", K. R. May deals with the physical aspects of sampling airborne microbes. The efficiencies of suction and impact systems, isokinetic and anisokinetic sampling, the effect of yaw and its avoidance and the new concept of stagnation point sampling are comprehensively examined. He reports on a limited number of sampling instruments only and it is noteworthy that the cascade impactor which he described in 1945 remains a standard reference instrument with which the efficiencies of others are compared, and the commonly used continuously recording spore trap of Hirst and size grading slit-sampler of Lidwell are based on it. Under the heading "Handling the Catch", W. C. Noble reviews the numerous techniques used to study airborne microbes ranging from algae to viruses.

In the section "Take Off and Landing of Particles", the "Liberation Mechanisms of Fungi" are naturally the

province of C. T. Ingold, who writes: "In the fungi the spores are essentially airborne". He gives details of the types of violent spore discharge, that brought about by the turgor of living cells, the not fully understood ballistospore discharge mechanism, the violent discharge of conidia, periodicity in spore release, and in the passive liberation of spores the effects of wind and rain. In "Take off of Bacteria and Viruses" O. M. Lidwell discusses the effects of talking, coughing and sneezing on the droplet discharge of *Streptococci*, desquamation in the dissemination of *Staphylococci* and dispersal into air from equipment, solid surfaces and by laboratory procedures. A. C. Chamberlain gives a detailed account of the physics of such processes as sedimentation, the impaction of particles on to the surfaces of vegetation, the resuspension of dust and the washout of particles from the atmosphere in rain. The final paper in this section, by H. A. Druett, is a most comprehensive account of the inhalation and retention of particles in the lung and nasal region in man.

In the section "Airborne Disease" D. Anderson and C. S. Cox consider the factors affecting the survival of bacteria in artificially generated aerosols. The survival of airborne bacteria appears to have received far more attention than that of the fungi, for among the 132 references cited by these workers, only one is concerned with fungi (*Aspergillus* and *Pestalotia*) and that published in the *Journal of Bacteriology*. J. E. Van der Plank, writing on the spread of plant pathogens in space and time, distinguishes between the spread of a pathogen and the dispersal of its propagules, with detailed reference to potato blight. J. M. Ogawa, D. H. Hall and P. A. Koepsell, writing about the spread of plant pathogens within crops as affected by life cycle and environment, state: "The least obvious, but very important phase of the life cycle of certain pathogens is the dispersal of their spores by air". In the light of this they discuss their investigations into control measures to prevent the dispersal of *Monilia laxa*, powdery mildew of plum and *Pseudoperonospora humuli*. The spread of airborne bacteria pathogenic for man is eruditely examined by R. E. O. Williams, who points out that they tend to be obligate pathogens and, unlike the fungal spores of plant pathogens, occur in the air indoors in small concentrations. Then he discusses airborne microbes in relation to pulmonary tuberculosis, inhalation anthrax, throat infections, pneumococcal pneumonia, pulmonary plague and the nasal carriage of *Staphylococci*. He stresses the difficulty in distinguishing between airborne infection and that acquired by other routes; that bacteria deposited in the upper respiratory tract induce infections at other sites, while the tubercle bacillus appears to be unique, for it cannot colonize the upper respiratory tract and infection begins at the periphery of the lung. He makes brief reference to sedimentation infection in operating rooms and concludes that the benefits of sanitary ventilation are too small to have a detectable effect on the incidence of infection. D. A. J. Tyrrell, concerned with the airborne spread of viruses of the respiratory tract, is confronted with the problem that air sampling for viruses is more complex than that for other microbes. His paper deals mainly with the epidemiology of respiratory disease in man, and possible routes of transmission. He describes experimental studies of the mechanisms of dispersion, such as the effect of coughing and sneezing in ejecting infected droplets, and stresses the need for a quantitative description of the transmission of infection.

In the last section, on microbial transport in the atmosphere and space, J. M. Hirst and A. W. Hurst are concerned with the long-distance transport of spores as inert particles, and have analysed spore catches obtained from aircraft flying downwind from a land source at various heights above the sea. They have traced a succession of diurnal spore clouds and have found that the clouds occurred where a meteorological analysis of air trajectories

suggested they should be. Vertical profiles and sections spore concentrations in relation to meteorological facts such as atmospheric turbulence and stability are discussed in detail and, after an examination of the importance of large pressure systems in the long-distance transport of spores, the authors conclude that distant transport is governed by the weather and not the climate or prevailing winds which just indicate the most frequent weather. C. W. Bruch describes the American Space Administration programme for determining the boundaries of the Earth's biosphere. He reports the response of microbes to some of the conditions in outer space, the effect of supersonic shock waves on microbes, the theories of panspermia in exobiology, and gives details of the techniques used for sampling microbes in the upper atmosphere with samples carried by balloons, and rocket-borne samplers for the collection of micrometeorites and microbes in space. It concludes with a note on the real-time (during flight) detection of atmospheric micro-organisms with techniques such as the fire-fly lantern enzyme reaction on adenine triphosphate.

This collection of papers, written independently by workers in disciplines ranging from physics to medical virology, has been edited to provide an up to date comprehensive and authoritative account, by two of the leading workers in the group which organized the symposium, and it is a tribute to their enthusiasm that such a coherent theme and exacting standard have been maintained throughout. The volume lists more than 800 references to airborne microbes and related topics and will be of value to workers in many fields who are concerned with the content of the air. R. R. DAVIES

## INTERACTION IN THE CELL

### The Cytology of the Protein Synthesis in an Animal Cell

By B. V. Kedrovskii. (Life Sciences: a Series of Monographs and Texts.) Pp. xi + 462. (New York and London: Gordon and Breach, 1965.) \$29.50.

This book was completed in October 1957, and the rapid progress in the field of protein biosynthesis during the ten years since then has resulted in the clarification of many of the problems which seemed obscure at that time. This is particularly true of such aspects as the role of nucleic acids and the mechanism of polypeptide synthesis which have been largely solved as a result of recent discoveries. Nevertheless, this study of the earlier literature serves as a timely reminder of the complexity of the interplay between the various parts of the animal cell, as well as between different cells, in the overall control of protein biosynthesis. These aspects of the synthesis of proteins in higher organisms are still not properly understood and this book provides a useful discussion of some of these problems.

The first part of the book consists of seven chapters dealing with investigations of protein synthesis during oögenesis of lepidoptera, mainly by cytochemical methods. These studies are essentially qualitative, and unfortunately the photographs are only in black-and-white and generally of poor quality. Furthermore, the figures and diagrams are often inadequately labelled and not clearly explained.

In the twelve chapters of the second part of the book protein synthesis in the animal cell is discussed with special reference to the function of the nucleus and cytoplasmic structures. The discussion of the biochemical mechanism of protein synthesis is, as already mentioned, necessarily incomplete and there are several more up to date reviews and books on these topics.

For these reasons, it is felt that this book is likely to be of only limited interest. The scanty bibliography and the absence of an index are further important drawbacks to its usefulness. H. R. V. ARNSTEIN

## ACID FOR METABOLIC CONJUGATION

### Glucuronic Acid, Free and Combined

Chemistry, Biochemistry, Pharmacology and Medicine. Edited by Geoffrey J. Dutton. Pp. xviii + 629. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 200s.

THE reader will agree that no defence is necessary for considering glucuronic acid to be a glucose metabolite of biochemical interest in its own right. Acceptance of this view will facilitate further progress in research of the role of this acid in living matter. Although historically glucuronic acid has been considered for a long time to be a conjugating radical made available by the body for detoxification purposes, this process is currently seen simply as one of the many recognized metabolic conjugations which have biochemical significance.

This book represents a valuable compilation of the published work relating to glucuronic acid, and some of the chapters are outstanding. One of these is the first chapter, by Marsh, discoverer of the saccharolactone pathway of glucuronic acid metabolism, which represents an authoritative, exhaustive but nevertheless readable treatment of the chemistry of D-glucuronic acid and its glycosides. There is an encyclopaedic list of all the glucosiduronic acids reported in the literature, and the degree of completeness of the evidence in support of their nature is indicated.

A central chapter written by the editor of the book is an honest, detailed survey of the development of our understanding of the mechanisms of glucuronic acid transfer reactions. That this understanding is far from complete is obvious when anyone searches for information about the nature of the enzyme UDP glucuronyl transferase and about the kinetics of the reaction it catalyses. In these circumstances resort to legal terms, such as "inadmissible evidence", seems out of place in the absence of all the facts regarding the nature of the transferase(s). Here, also, "multiplicity" of transferases seems to lack biochemical definition.

Levy and Conchie's noteworthy studies on aldono-lactone inhibition of glycosidases are included. Their statement that the lysosome theory begs the whole question of the *in vivo* action of acid hydrolases will fall on an increasing number of receptive ears today.

Jayle and Pasqualini's review of steroids and thyroxine, Silbert's of polysaccharides, Smith and Williams's of drugs and Schmidt and Lester's of bilirubin, are all written in a manner which is both informative and readable. A valuable feature of the book is the collection of analytical methods at the end of several chapters. I recommend the book for the serious student and investigator in biochemistry, pharmacology and medicine.

WILLIAM H. FISHMAN

## COMPOUNDS HOLD TOGETHER

### Structure and Bonding

Vol. 1. Edited by C. K. Jørgensen, J. B. Neilands, R. S. Nyholm, D. Reinen and R. J. P. Williams. Pp. 281. (Berlin and New York: Springer-Verlag, 1966.) 48 D.M.

THIS new review series is intended to appear at irregular intervals and to deal with problems in chemical structure and bonding in modern inorganic chemistry, chemical physics and biochemistry.

The first volume contains nine reviews received between January and May 1966. "Recent Progress in Ligand Field Theory", by C. K. Jørgensen, is based on lectures given at the Summer School on Ligand Field Theory held at Constance in September 1962. This gives a brief account of the interpretation of electronic spectra of

transition metal complexes and of refinements of electrostatic ligand field theory. "The Ambident Nature of Cyanide", by D. F. Shriver, is a clear review of structures containing the bifunctional cyanide ligand.

Three fully documented biochemical articles occupy half the volume. "Naturally Occurring Non-porphyrin Iron Compounds", by J. B. Neilands, deals mainly with iron(III) hydroxamates. These stable complexes seem to carry iron through metabolic channels and insert it into porphyrins, enzymes and proteins. "The Chemistry and Function of Ferredoxin" is by B. B. Buchanan, and describes the non-haem iron protein, which plays an important part in the action of anaerobic fermentative bacteria, in photosynthetic bacteria and in plant photosynthesis. "The Transferrins", by R. E. Feeney and S. K. Komatsu, concerns the homologous proteins found in various fluids of vertebrate animals; for example, blood serum, milk and egg-white (conalbumin).

Three of the final group of four articles are revised versions of lectures given at the Symposium on Soft and Hard Acids and Bases held at the Cynamide European Research Institute at Cologny in May 1965. "Factors Contributing to (b)-behaviour in Acceptors", by S. Ahrland, resembles another article by the same author (*Svensk Kemisk Tidskrift*, 77, 584; 1965) and is an outgrowth of Ahrland, Chatt and Davies's original division of metal ions into classes (a) and (b) on the basis of their affinity sequences for donor atoms. "The Classification of Acceptors and Donors in Inorganic Reactions", contributed by R. J. P. Williams and J. D. Hale, is a more critical account of the inter-relations of the (a) and (b) classification, Pearson's hard and soft terminology and polarizability. "Electronic Polarizability, Innocent Ligands and Spectroscopic Oxidation States", by C. K. Jørgensen, also discusses these concepts. Finally, there is "Displacement Reactions and the Concept of Soft and Hard Acids and Bases", by R. F. Hudson, which describes correlations of rate constants with various properties of nucleophiles.

The first volume has no index and the five editors have not quite achieved a common format. It is not yet clear whether this particular marriage of chemistry and biochemistry will be happy. The soft back is rather highly priced for the individual, but is an essential purchase for chemical and biochemical libraries. It contains much to interest, stimulate and provoke.

F. J. C. ROSSOTTI

## IMMUNOLOGICAL DANGER

### Delayed Hypersensitivity

By J. L. Turk. (North-Holland Research Monographs: Frontiers of Biology, Vol. 4.) Pp. ix + 252. (Amsterdam: North-Holland Publishing Company, 1967.) 80s.

SYMPOSIA on delayed hypersensitivity commonly begin with a discussion of the definition of the term. This usually ends inconclusively, and accurately indicates our confusion and lack of understanding of this phenomenon. Hypersensitivity, however, is commonly defined as an immunological reaction harmful to the body, and the term "delayed" refers to the interval that is observed between the injection of antigen into a sensitized animal and the development of an inflammatory reaction at this site. The phenomenon was first described as characteristic of hypersensitivity to bacteria and was initially termed "bacterial allergy". The phrase "delayed-type hypersensitivity" was introduced by Chase, who obtained such delayed, slowly developing reactions, not only with bacteria but also with purified antigens of various types. The next crucial finding was again made by Chase who, in collaboration with Landsteiner, discovered that passive transfer of delayed-type hypersensitivity could not be achieved with serum, that is circulating antibodies, but could be so transferred with lymphoid cells or cells from

peritoneal exudates. Our present concept of delayed hypersensitivity is based very largely on the experiments of Chase and his collaborators. Most workers agree that the passive transfer by lymphoid cells and the demonstrable unimportance of circulating antibody are the essential criteria which characterize delayed hypersensitivity. As such it seems to represent a separate aspect of the immune response in general, and is now sometimes termed cell-mediated immunity or hypersensitivity. By these criteria certain important biological phenomena can be considered examples of delayed hypersensitivity. Instances that can be cited are the rejection of skin or organ grafts by incompatible recipients, or the similar reactions to tumours, either implanted or arising *de novo* in response to viral or chemical stimulation. There is also the possibility, although it is not yet convincingly proved, that certain "auto-allergic" experimentally induced pathological lesions, for example encephalitis or thyroiditis, may be, at least in part, further examples. In its simplest form of an acute, transient, but slowly developing inflammatory reaction to the local presence of antigen there are many examples, bacterial or non-bacterial.

The most superficial study of delayed hypersensitivity immediately reveals a number of very important and unsolved problems. Examination of immunoglobulins is lending clarity to some aspects of immunology, but delayed hypersensitivity remains in a miasma of uncertainty that is all the more frustrating, because, as a phenomenon, it is likely to be of great importance both to immunology and to some of the most serious problems of contemporary clinical medicine.

Dr Turk has himself made distinguished contributions to our knowledge of delayed hypersensitivity and has had the courage to present and discuss the mass of experimental data, much of it conflicting, that has now accumulated. Doubts are expressed from time to time as to the wisdom of producing "hard cover" monographs on subjects that are the object of intensive current research and controversy and where views are likely to change rapidly. On the other hand, review articles seldom provide space for a full critical study of such a large field. The complexity and importance of the subject further justify the venture.

One of Dr Turk's principal problems has clearly been to decide what to include in his terms of reference or indeed whether to regard cell mediated hypersensitivity as an entity or as an immunological rag-bag. He has wisely steered a middle course and included practically every phenomenon that could be considered relevant without committing himself as to whether it will prove ultimately to be so. The exception is tumour immunity, which is not given a separate section although it might well have done so, especially in view of the high quality of some of the work now being carried out in this field, once regarded as the "lunatic fringe" of both cancer studies and immunology. In general, in his choice of topics, Dr Turk has inevitably been guided by the criteria quoted here and based on the work of Chase and his predecessors.

The first part of the book is devoted to "classical" experimental delayed hypersensitivity, that is, slowly developing but transient inflammatory reactions in skin provoked by local injection of antigen into a suitably sensitized host. This section is unexciting but definitive. The author then deals with homograft reactions in the light of the part played by delayed hypersensitivity, and next discusses unresponsiveness from the point of view of the light shed by various unresponsive states on the basic mechanism of delayed hypersensitivity. In this context, however, "light" is a relative term. In the next chapter Dr Turk deals with his own *forte*, the events in local lymph nodes during delayed hypersensitivity. The next topic is antigenic specificity in delayed hypersensitivity, especially in relation to the intriguing experiments of Benacerraf, Gell, Leskowitz and others. This induces the feeling, commonly experienced while reading about

delayed hypersensitivity, that the results are of basic importance even if not fully understood.

The most crucial section is left until last, and that is the role of antibody in delayed hypersensitivity and the role of delayed hypersensitivity in antibody production. After a succinct survey of the available evidence he comes down fairly firmly against antibody as we know it playing an important part in delayed hypersensitivity, including the so-called cytophilic antibody. He takes less than two pages to make a similar decision against delayed hypersensitivity as a stage (at which arrest may occur) in the production of classical antibody, preferring the view that it is a separate phenomenon.

Earlier in the book Dr Turk weighs the evidence linking delayed hypersensitivity and cellular immunity (for example in tuberculosis) and concludes that there is no justification for assuming a direct relationship. It may be that this hoary ghost has at last been exorcized or it may be that it will rise again to haunt us. Dr Turk has more trouble with his discussion of the respective roles of macrophages and lymphocytes in delayed hypersensitivity and does not entirely succeed in disentangling for the reader the conflicting experimental evidence, although he certainly cannot be blamed for this.

Nevertheless, the author deserves congratulations for his careful assessment of the results of others and for the reasoned conclusions he draws from them. Not everyone will agree with his evaluation of individual pieces of research, but many will be grateful where he makes order out of chaos. This is an instance where the reviewer's cliché that an author has performed a valuable service is more than justified.

W. G. SPECTOR

## BRAIN AND HORMONES

### Neuroendocrinology

Edited by Luciano Martini and William F. Ganong. Vol. 1. Pp. xx+774. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 260s.

In the past twenty years the study of the mutual interaction of the central nervous system and the glands of internal secretion has been one of the most active areas of experimental endocrinology. A major part of this work has been concerned with the details of the mechanism by which the hypothalamus, through the anterior pituitary, affects the activity of the gonads, adrenal cortex and the thyroid gland. During this period the use of a wide range of techniques, previously not often encountered in endocrine research laboratories, has become common. Some of the methods employed are sectioning of the pituitary stalk, transplantation of the pituitary, cultivation of pituitary fragments *in vitro*, the destruction of discrete areas of the hypothalamus by stereotaxic methods, electrical stimulation of the brain in the conscious animal, electrical recording from groups of neurones or single cells, cannulation of the pituitary, and the injection or implantation of hormones into the pituitary or hypothalamus. Employing these novel techniques and, more importantly, sharing a few basic concepts, research workers with a wide range of interests have found themselves grouped together and their common field of study, brain-hormone interactions, has been designated "neuroendocrinology". This book, published under that title, illustrates the range and volume of recent and current work that may be classified under this heading.

A concise introductory chapter by Ganong is followed by a detailed account of the anatomy, gross and microscopic, of the hypothalamus and pituitary by Daniel. Particular attention is rightly paid to the vascular connections, the hypothalamo-hypophysial portal vessels, that form the essential functional link between the brain

and the adenohypophysis. The neural connexions of the hypothalamus and the limbic system are reviewed by De Groot, but here, and elsewhere in the book, the fact that no agreed or precise function, in the control of endocrine activity, can be ascribed to extra hypothalamic structures indicates where limitations in present techniques leave gaps in our knowledge. A survey of lesion making techniques and a useful listing of stereotaxic brain atlases for different species follow, and bring us to an important chapter on neurosecretion. Bern and Knowles deal extensively with this difficult topic, drawing their examples and their excellent illustrations from many different species. Their definition of a neurosecretory neurone on a functional basis is stimulating and seems likely to provoke much discussion.

A series of reviews of specific topics follows. Two critical but balanced chapters by Sawyer and Mills, and by Cross, deal with the control of secretion of the vasopressin and oxytocin. The value of these is greatly increased by the fact that they have not confined themselves to purely neuroendocrinological topics but include discussions on such problems as assay methods and the physiological significance of the various actions of oxytocin. The chapter by McCann and Dhariwal on hypothalamic releasing factors is a good survey of the physiology of this sometimes contentious field, though not all workers would agree with their assessment of the physiological significance of the fact that vasopressin can act on the anterior pituitary to cause the secretion of adrenocorticotrophic hormone, that is as a corticotrophin releasing factor or CRF. Their conclusion that the releasing factors are polypeptides may need to be revised in the light of more recent findings that were not available to them at the time their contribution was written. The remainder of the book deals mainly with the control of the secretion of specific pituitary trophic hormones; an interesting and successful innovation is a separate discussion of the secretion of gonadotrophin in the male by Davidson. The general standard of these chapters is high, but three are of particular interest. Reichlin deals comprehensively with the pituitary-thyroid system, emphasizing the necessity for an integrative approach that considers the interaction of a "neural" stimulus from the hypothalamus and a "humoral" feedback control, taking into account the physico-chemical state of the target organ hormone in the blood and variations in the rate of disposal by the peripheral tissues. Mulrow discusses the control of aldosterone secretion, giving due attention to neural factors, established and postulated, but also to the renin-angiotensin system and other influences on the adrenal cortex. Meites, in a wide ranging review, gives a detailed account not only of the neuroendocrine but also of the many other factors that must be considered in the discussion of the physiological control of mammary gland growth and lactation. There is some danger that to concentrate exclusively on purely neural factors may lead to neglect of the other mechanisms that can affect the activity of the endocrine glands. These three articles show how the importance of neuroendocrine control is best seen in the context of a wider analysis of system function in the whole animal.

This volume has been produced and edited to a high standard, but a confusing transposition of lines was noted in the section on neurosecretion (page 146) and one *non requitur* (section VB, page 546 of Chapter 13) appears to have escaped notice. The other aspect of brain-hormone interaction, the study of the effects of hormones on the central nervous system, will be the main theme of a second volume from the same editors. Together the two volumes should provide a detailed and comprehensive survey of the literature of a rapidly developing but rather diffuse subject that will be of value to the research worker and to the senior student who has already acquired a sound basic knowledge of endocrinology.

K. BROWN-GRANT

## University News:

## Liverpool

MR F. SAWKO, reader in civil engineering in the University of Leeds, has been appointed to the new second chair in civil engineering, and Mr R. K. Penny, assistant director of research in the University of Cambridge, has been appointed to the new chair of engineering design and production.

## London

THE following titles have been conferred: professor of mechanical engineering, on Dr T. H. Lambert, in respect of his post at University College; professor of physics, on Dr D. H. Martin, in respect of his post at Queen Mary College; professor of rational mechanics, on Dr F. A. E. Pirani, in respect of his post at King's College; professor of psychology, on Dr P. H. Venable, in respect of his post at Birkbeck College; reader in electrical engineering, on Dr R. M. Redwood, in respect of his post at Queen Mary College. Professor D. V. Lindley, professor of statistics in the University College of Wales, Aberystwyth, has been appointed to the chair of statistics tenable at University College, and Dr J. H. E. Cohn, lecturer in mathematics at Bedford College, has been appointed to the readership in mathematics tenable at Royal Holloway College.

# CORRESPONDENCE

## What Place for Engineers?

SIR,—On June 17 you commented on Professor Thring's article advocating the establishment of an academy for engineers. Much of this discussion was based on the example of the recently created National Academy of Engineering in the United States which, as you rightly said, has a number of features which would not easily fit into the British scene. May I draw your attention to the experience of an earlier and well-tried example of engineering academy, namely, the Royal Swedish Academy of Engineering Sciences (Ingeniörsvetenskapsakademien, IVA)? This body, having developed in a European country, has many features worth considering in relation to present British engineering and industrial needs.

The Swedish Academy, established in 1919 and hence the first of its kind in the world, was a deliberate attempt on the part of an influential group of Swedish industrialists and engineers to correct a national situation. Sweden has for long enjoyed an eminence in fundamental research which is great in relation to the size of the population. By the end of the First World War, however, the draw of academic research was so strong that industry became concerned that only a small proportion of the best scientific minds of the country were willing to take up applied work. A conscious attempt was therefore made to create a centre for the applied sciences with status and scientific acceptance to provide a reasonable balance of attraction. The decision was not to create an engineering academy in the general sense, but a Royal Academy of Engineering Sciences. This was done with the personal interest and participation of the King, who became its patron. The director of the Academy was given the title of Professor to provide the necessary academic respectability and the Crown Prince attended a number of early meetings, thus symbolizing the importance of the new institution in the eyes of the State.

The result has been outstandingly successful and, although it would be extravagant to claim that the success of Sweden during the past few decades in creating highly competitive science based industries is due to the Academy, nevertheless its part has been very great. IVA has not only succeeded in achieving for the engineer

a high status in society and public interest in his work, but has greatly encouraged the penetration of the scientific approach within engineering itself.

The Academy has been particularly fortunate in having at its head three outstanding men: Axel Enström, Edy Velander and now Sven Brökhult, very different personalities but each uniquely appropriate for the phase of development which he has led.

An important feature of IVA's activity is the annual commemoration meeting held each October on the anniversary of the granting of its charter. This is a splendid occasion, attended generally by the king and the élite of Sweden in addition to the members of the Academy, at which the director is bound by constitution to deliver a survey of the development of science and technology during the past year. This has provided a series of brilliantly staged demonstrations and lectures on new technological developments which have brought to the attention of the informed public many of the important applications of science, often long before their significance has been generally recognized.

This is not the place to describe the work of IVA in detail. But it should be mentioned that it consists of a maximum of 200 persons under 65 years of age. There are ten sections—mechanical, electrotechnical, building, chemical, mining and metallurgical science, computer engineering, basic science, forest and wood technology, economics and biotechnics. Each section is allotted a statutory number of seats. Once a member reaches the age of 65, his seat is no longer counted (although his membership continues) and a new member can be elected. This arrangement enables a steady rejuvenation of the body. Members are engineering scientists of prominence from industry, higher education and research institutes. IVA has done much to promote the establishment of new research institutes, particularly for borderline subjects, and is frequently called on to advise the government.

Far from exacerbating the difference between scientists and engineers which you fear, IVA has built a bridge between them and has the respect and support of the academic scientists.

Yours faithfully,

ALEXANDER KING

Director for Scientific Affairs,  
OECD,  
Paris.

### Applying Research

SIR,—While one would agree that some of the points made by Professor Temperley (*Nature*, 214, 1378; 1967) are valid, I would like to take issue with one of them.

He says that he "once interviewed a distinguished PhD of several years' standing whose job was to devise schedules of cutting up steel rod and plate in order to fill orders with minimum wastage!". Professor Temperley hoped this was a very extreme case of inefficient use of scientists.

In fact this particular problem is very important. In the special case of minimizing waste in cutting orders out of steel plate it is mathematically intricate and poses great difficulties. This, however, is not the point at issue, which is the value of this sort of work to the steel industry.

At present about 4 per cent of steel production is waste, due, amongst other things, to the problem of cutting up orders out of batches of steel. This represents an annual loss of about £6m a year. Hence, although at first sight this seems a trivial problem, it is, on a national scale, most important, and any PhD scientist who could save a few per cent of this £6m would be making a sizable contribution to his employers' economic wellbeing. In addition, of course, general solutions to this problem could be applied not only throughout the steel industry but also to other industries, including glass and paper

manufacture where similar problems arise and where important economies remain to be effected.

Yours faithfully,

B. H. P. RIVETT

University of Lancaster,  
Skein House,  
Queen Square, Lancaster.

### Titles

SIR,—I have read the letter from Mr Eugene Munroe in *Nature* (214, 1064; 1967) concerning titles. I trust that you will not be swayed by his arguments.

Surely the function of the titles of articles in *Nature* about general scientific policy is that they should be "catch-reader". Far too few scientists, I fancy, concern themselves with such matters and anything which can trap them into broadening their outlook and thinking is to be welcomed. To set against this socially desirable end the convenience of people who want to have "a card file on scientific policy" is to be irresponsible to the scientific community as a whole.

Yours faithfully,

D. W. EWER

Department of Zoology,  
University of Ghana,  
P.O. Box 67,  
Legon, Accra,  
Ghana.

### Pharmacology

SIR,—A drug has been defined as "any chemical substance that, administered to a living organism (or its part), gives rise to a scientific paper". Although drugs may be administered for other purposes than scientific investigation, this purpose concerns us now.

Reading through the classified list of Letters to the Editor in this week's *Nature* (July 1, 1967), I notice six letters on the effects of drugs, but no heading of Pharmacology, which is the science of drugs. One of these letters is placed under Physiology ("Inhibition of Gastric Acid Secretion by a Purified Bacterial Lipopolysaccharide"). Two are under Pathology ("Effect of Cyclophosphamide, 6-Mercaptopurine or Methotrexate on the Furth Rat Leukaemia" and "Demonstration of Copper and Acid Phosphatase Activity in Hepatocyte Lysosomes in Experimental Copper Toxicity"). Another pharmacological letter is placed under Biochemistry ("Effect of Actinomycin on Protein Synthesis by Lymphocytes"). The fifth letter is under Microbiology ("Action of Ethidium Bromide on Growth of Herpes Virus in Cell Cultures") and the sixth under Biology ("Toxicity of Tobacco Smoke to the Spotted Alfalfa Aphid *Therioaphis maculata* (Buckton)").

Concerned as it is with the use of chemical substances to explore the nature of life, pharmacology is a meeting point of chemistry and biology and therefore a subject that is growing fast. To deny it a place among the headings of your letters distorts the picture of how work is distributed in the various fields of research. It also forces pharmacologists to search harder for what they ought to read. Does this forced searching not deny a simple extension of your own thesis that "the professional reader is the one most concerned to know precisely what claim on his attention an article sets out to make" (*Nature*, June 10, 1967, Vol. 214, p. 1078)?

The removal of the subject head Pharmacology from the classification of Letters to the Editor is not a pleasing change.

Yours faithfully,

H. O. J. COLLIER

Department of Pharmacological Research,  
Parke, Davis and Company,  
Hounslow, Middlesex.

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

**LABORATORY TECHNICIAN** in the DEPARTMENT OF BIOLOGY AND CELL BIOLOGY to assist (a) with the preparation of classwork and (b) with histochemical and biochemical research—The Clerk to the Governing Body, Colwich Polytechnic, Wellington Street, London, S.E.18 (July 28).

**LECTURER IN PHYSICS**—The Secretary, St. Mary's Hospital Medical School (University of London), Paddington, London, W.2 (July 29).

**COMPUTER PROGRAMMER** (with a good honours degree in mathematics or pure or applied science, and experience of computer programming and numerical analysis) in the DEPARTMENT OF ELECTRICAL AND ELECTRONIC ENGINEERING—The Registrar and Secretary, The University, Leeds, 2 (July 31).

**LECTURER** (preferably with experience in immunochemistry) in the SENIOR RESEARCH UNIT, DEPARTMENT OF CLINICAL BIOCHEMISTRY—The Registrar, The University, Newcastle upon Tyne (July 31).

**RESEARCH ASSISTANT** (with previous programming experience, and preferably some statistical training) to develop methods of using computers analysis of results of medical examinations—Dr. W. W. Holland, Department of Clinical Epidemiology and Social Medicine, St. Thomas's Hospital Medical School, London, S.E.1 (July 31).

**RESEARCH FELLOW** (with a Ph.D. or the equivalent and at least some experience in biochemical research) in BIOCHEMISTRY or CELLULAR PHYSIOLOGY to take part in a research project on the mode of action of the thyroid hormones—Prof. J. R. Bronk, Department of Biology, University of York, Heslington, York (July 31).

**ASSISTANT EXPERIMENTAL OFFICER** (with a degree in botany or agricultural botany) to work on the physiology of growth and yield of field crops, particularly on root growth and on effects of growth regulators—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (August 4).

**LECTURER IN GEOPHYSICS** in the DEPARTMENT OF GEOLOGY—The Registrar and Secretary, Old Shire Hall, University of Durham, Durham (August 4).

**NERC SENIOR RESEARCH ASSISTANT or RESEARCH ASSISTANT** (preferably with qualifications in physics or electronic engineering) in MARINE GEOPHYSICS to take part in a programme of geophysical investigations of the crust and mantle in the North-Eastern Atlantic and on the British Continental shelf—The Registrar and Secretary, Old Shire Hall, University of Durham, Durham (August 4).

**ASSISTANT LECTURER or LECTURER** (with special qualifications in moral philosophy) in PHILOSOPHY—The Registrar (Room 39, O.R.B.), The University, Reading, Berkshire (August 5).

**ASSISTANT LECTURER and a LECTURER** (experienced in the use of high speed digital computers and an interest in numerical analysis, statistics or operational research) in COMPUTATION in the DEPARTMENT OF MATHEMATICS—The Registrar, University of Manchester Institute of Science and Technology, Sackville Street, Manchester, 1 (August 7).

**LECTURER or ASSISTANT LECTURER** (preferably with research interests in operational research or the computational aspects of statistics) in the ELECTRONIC COMPUTING LABORATORY—The Registrar, The University, Leeds, 2 (August 7).

**SENIOR LECTURER** in the DEPARTMENT OF PSYCHIATRY—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (August 7).

**CHAIR OF PHARMACOLOGY**—The Secretary of the University Court, The University, Glasgow (August 11).

**LECTURER or ASSISTANT LECTURER** (with a good honours degree or equivalent qualification) in SOCIOLOGY—The Academic Registrar, The City University, St. John Street, London, E.C.1, quoting Ref. 41/SS (August 11).

**RESEARCH ASSISTANT** (science graduate, either in chemistry or in biochemistry) in DERMATOLOGY to undertake work on the histochemistry of the skin with special reference to steroid synthesis—The Secretary of the University Court, The University, Glasgow (August 11).

**LECTURER IN ENGINEERING** (Materials Science); a **LECTURER IN ENGINEERING** (Mechanical/Electrical); and a **LECTURER IN CIVIL ENGINEERING** at the University College of Townsville, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, W.1 (Australia and London, August 12).

**DEMONSTRATOR** (graduate or about to graduate) in BIOLOGY—The Registrar, The University, Keele, Staffordshire (August 14).

**TECHNICAL OFFICER/RESEARCH ASSISTANT** (experienced in conventional analytical techniques and preferably experienced in radio-chemistry) in the DEPARTMENT OF GEOPHYSICS AND GEOCHEMISTRY, Research School of Physical Sciences, to use and develop neutron activation methods in a research programme concerned with elemental abundances in meteorites, minerals and rocks—The Bursar, Australian National University, Box 4 P.O., Canberra, A.C.T., Australia (August 14).

**LECTURER** (with a special interest in any systematic aspect of geography and a wish to obtain a regional interest in Africa) in GEOGRAPHY—The Assistant Registrar (Establishment), The University of Sussex, Essex House, Falmer, Brighton, Sussex, quoting Ref. 911/2 (August 15).

**RESEARCH ASSISTANT** (with a good honours degree in psychology or a related subject) in the DEPARTMENT OF PSYCHOLOGY—The Registrar, The University, Newcastle upon Tyne (August 15).

**SENIOR LECTURERS (2) IN SURGERY** at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 18).

**CHEMIST, BIOCHEMIST or MICROBIOLOGIST** (with an honours degree or equivalent) in the ANIMAL SCIENCES DIVISION of An Foras Taluntais (The Agricultural Institute) to carry out research on the problems associated with extending the shelf life of packaged fresh meat—The Director, An Foras Taluntais, 33 Merrion Road, Dublin 4, Republic of Ireland (August 21).

**PROFESSOR OF CHEMICAL PATHOLOGY**; **PROFESSOR OF OPHTHALMOLOGY**; and a **PROFESSOR OF RADIOLOGY** at the University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, W.C.1 (August 21).

**LECTURER and an ASSISTANT LECTURER** (with a good honours degree in a relevant subject) in MATERIALS SCIENCE in the DEPARTMENT OF MECHANICAL ENGINEERING—The Secretary of the University Court, The University, Glasgow (August 26).

**ASSISTANT LECTURER** in SOCIAL AND PREVENTIVE MEDICINE (statistical aspects) (a medical qualification is not necessary)—The Secretary, The Queen's University, Belfast, Northern Ireland (August 31).

**CHAIR OF DENTAL PROSTHETICS**—The Registrar, The University, Newcastle upon Tyne (August 31).

**CHAIR OF MICROBIOLOGY** at the University of Hong Kong—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Hong Kong and London, August 31).

**LECTURER or SENIOR LECTURER** (with a qualification in photogrammetry and photogrammetric engineering from a University or other recognized

institution, and preferably a degree or other qualification in surveying or civil engineering, and some teaching and professional experience) in PHOTOGRAMMETRY at the University of Otago, Dunedin, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, August 31).

**LECTURER** (with a good honours degree in engineering or an equivalent qualification and preferably industrial experience in mechanical engineering design) in MECHANICAL ENGINEERING DESIGN—The Registrar, University of Strathclyde, George Street, Glasgow, C.1 (August 31).

**SENIOR LECTURER or LECTURER** (suitably qualified and interested in solid state studies or atmospheric physics) in PHYSICS at the University of Canterbury, Christchurch, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (August 31).

**LECTURER IN PHYSICS** at the University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 2).

**READER** (with a degree in mechanical engineering at least at Master's level) in MECHANICAL ENGINEERING; and a **SENIOR LECTURER or LECTURER** (with a degree in mechanical engineering, preferably at honours level, of a recognized Commonwealth university, together with either experience in industry, or research and teaching experience at university level) in MECHANICAL ENGINEERING at the University of Canterbury, Christchurch, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (September 15).

**CHAIR OF COMPUTER SCIENCE**—The Registrar, University of Warwick, Coventry, Warwickshire (September 30).

**CHAIR OF BOTANY**—The Secretary, The Queen's University, Belfast, Northern Ireland (October 14).

**FORBES CHAIR OF ORGANIC CHEMISTRY**—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (October 31).

**ASSISTANT BIOCHEMIST** (preferably with previous experience in protein chemistry) to assist in the supervision of the production and testing of blood plasma protein fractions for clinical use in hospitals and to participate in associated research and development work—The Secretary, The Lister Institute of Preventive Medicine, Elstree, Herts.

**DEMONSTRATOR** (graduate in biochemistry, microbiology or chemistry); and a **RESEARCH ASSISTANT** (graduate in biochemistry, microbiology or chemistry) in the DEPARTMENT OF BIOCHEMISTRY AND AGRICULTURAL BIOCHEMISTRY—The Registrar, University of Wales, Aberystwyth.

**LIBRARIAN and INFORMATION OFFICER** (preferably with a scientific qualification) to take charge of the library and archives, information and public relations and to be editor of the Institution's publications—The Royal Institution, 21 Albemarle Street, London, W.1.

**PROFESSOR OF COMPUTER SCIENCE**—The Registrar (Room 39, O.R.B.), The University, Reading, Berkshire.

**SENIOR RESEARCH TECHNICIAN** for interesting and varied work on immunity in reticuloses and other malignant diseases—Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, quoting Project No. 863, Ref.: ASCE1089.

## HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

\*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.....£14.0.0 each  
United States of America.....(by air freight).....\$44 each  
Canada.....(by air freight).....\$47.80 each  
Elsewhere overseas by surface mail.....£13.15.0 each

(Charge for delivery by air mail on application)

\*Shorter periods *pro rata*. (Minimum three months.)

### MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

12 MONTHS (52 issues and 4 indexes)

Number of Copies	G.B. & Eire	U.S.A. (by air freight)	Canada (by air freight)	Elsewhere (surface mail)
3–5	Each £13.10.0	Each \$42	Each \$46.00	Each £13.10.0
6–11	£12.15.0	\$40	\$43.60	£12.15.0
12 or more	£12.0.0	\$38	\$41.70	£12.0.0

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

## Up-Date Your Spectrophotometer For Increased Accuracy, Greater Productivity

Many older spectrophotometers have excellent optics, but the usefulness is limited by outmoded surrounding electronics.

Now you can change all that!

The investment made in hundreds of these units has been protected by the Gilford Spectrophotometer Modernization Program. Accuracy has been up-graded, operation made simpler, and chance for error in readings reduced.

Gilford has developed Model 222 equipment just for this purpose. It may be used with most leading makes of spectrophotometric monochromators.

The Model 222 solid-state power supply smooths

out and regulates power for both the input light source and the output sensing equipment. This assures accuracy and dependability of light input and three decade output reporting.

The Gilford 222 Photometric Unit reports absorbance directly with linear digital indication from zero to 3 A. Sensitivity to 0.001 A. Drift less than 0.005 A per hour.

Find out how little it will cost you to bring your present spectrophotometer up-to-date. Complete and mail the coupon below, or better still, cable us:

GILLAB, U.S.A.

Gilford Instrument Laboratories, Inc.  
Oberlin, Ohio 44074

Gentlemen:  
We have a (Make and Model) \_\_\_\_\_ Spectrophotometer.  
Please send us your full information and estimate of the cost of up-dating this instrument with  
Gilford 222 equipment.

Name \_\_\_\_\_

Address \_\_\_\_\_

City \_\_\_\_\_ State \_\_\_\_\_ Zip \_\_\_\_\_

### Classified Advertisements

Semi-displayed £4 16s. per single column inch. Minimum £2, each additional 1/12th of an inch 8s. Full page £132. Half page across £66. Colour (orange) £15 extra. 1s. is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, Strand, London, W.C.2. Telephone: 01-405 4743. Telegrams: Textualist, London, W.C.2.

### APPOINTMENTS VACANT

#### COMMONWEALTH AGRICULTURAL BUREAUX COMMONWEALTH INSTITUTE OF BIOLOGICAL CONTROL

Two vacancies exist for **Entomologists** for field work on biocontrol projects. Qualifications: honours degree in biology with emphasis on entomology and practical postgraduate experience, preferably in biocontrol. Salary, according to age, qualifications and experience, in scale £1,099 to £3,578. Provision for superannuation. Candidates will be posted to one of the Institute's stations in India, Pakistan, East Africa, West Indies, Europe, and South America, and must be prepared to travel extensively.

Further information and application forms from Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks, England. Applications must be submitted not later than October 15, 1967. Government employees must apply through official channels. (X120)

#### Brighton Education Committee

#### BRIGHTON COLLEGE OF TECHNOLOGY

#### RESEARCH ASSISTANTS

Vacancies exist in a wide range of projects in the following departments of the College:

COMPUTING and CYBERNETICS; MANAGEMENT and BUSINESS STUDIES (particularly in the fields of multi-access systems and the theory of automata); APPLIED PHYSICS; APPLIED CHEMISTRY; PHARMACY; MECHANICAL and PRODUCTION ENGINEERING; ELECTRICAL and ELECTRONIC ENGINEERING; CIVIL ENGINEERING and BUILDING.

Remuneration: £810 by £30 to £870 per annum.

Further particulars and application forms, to be returned as soon as possible, from the Registrar, Brighton College of Technology, MOULSECOOMB, Brighton 7. (306)

#### QUEEN ELIZABETH COLLEGE (UNIVERSITY OF LONDON) CAMPDEN HILL ROAD, W.8 CHEMISTRY DEPARTMENT

**Research Assistant** required for an investigation of the synthesis of new unsaturated carbohydrate derivatives for testing as anti-tumour agents, financed by a grant from the British Empire Cancer Campaign. Candidates should hold a good Honours degree in chemistry. Salary £750.

Applications, giving age, education, and experience, should reach Professor L. Hough by August 5. (321)

**TECHNICAL ASSISTANT REQUIRED** to take part in a research project into the structure and function of invertebrate nervous systems using various modern techniques. In particular a new AEI 6G electron microscope has been provided for this project, which is supported by the Science Research Council. The status of the position will depend on the experience of the applicant, but the salary will in any case not be less than £680 per annum.—Applications, in writing only, should be sent to Professor G. M. Hughes, Department of Zoology, The University, Bristol, 8, by August 1, and should include age, qualifications, and experience to date, and names of two referees. (317)

## Scientific Civil Service

### MINISTRY OF OVERSEAS DEVELOPMENT ANTI-LOCUST RESEARCH CENTRE

LONDON, W.8

**PRINCIPAL SCIENTIFIC OFFICERS** (2 posts) required for permanent established home-based posts.

These posts have been created to meet requests from overseas governments for Plant Protection Officers to plan and conduct relevant research and to initiate or give advice on crop pest-control practice. Officers will spend most of their time overseas on secondment to overseas governments but they will be members of the Scientific Civil Service and be based on the Anti-Locust Research Centre, which will provide them with the technical information and home-base facilities required in connection with their overseas assignments.

**QUALIFICATIONS:** Normally degree with 1st or 2nd class honours, or equivalent or higher qualification, in biology, preferably with specialisation in entomology and experience of plant protection overseas.

**SALARY:** £2,335 to £3,192; starting salary may be above minimum. Foreign Service allowance payable when overseas. Promotion prospects.

**WRITE** to Civil Service Commission, Savile Row, London W.1, for application form, quoting S/6726/67. Closing date August 9, 1967.

### MINISTRY OF AGRICULTURE, FISHERIES AND FOOD INFESTATION CONTROL LABORATORY

Hook Rise South, Tolworth, Surrey

**ZOOLOGIST/PHYSIOLOGIST** (graded E.O./A.E.O.) with biological and/or biochemical background to participate in a research programme for the preparation of new rodenticides; to assist in screening compounds for rodenticidal activity; and to undertake literature surveys. Working knowledge of French or German an advantage.

**QUALIFICATIONS:** Degree or equivalent in Zoology or Physiology. Under 22, minimum qualification is G.C.E. in five subjects; including two Scientific/Mathematical subjects at 'A' level. One of these must be in Zoology or Physiology.

**SALARY:** A.E.O. £568 (at 18) to £803 (at 22) to £1,017 (at 26 or over) to £1,243; E.O. (minimum age 26) £1,365 to £1,734.

Prospect of permanent pensionable appointment.

**APPLICATION FORMS** from Ministry of Agriculture, Fisheries and Food, Room 625, Great Westminster House, Horseferry Road, London S.W.1, quoting E.P.9360. Closing date for applications, August 8, 1967. (274)

#### OLDCHURCH HOSPITAL ROMFORD, ESSEX

(651 Beds)

**RESEARCH ASSISTANT** (Biochemist) for an investigation of oestrogens in relation to infertility. Preferably a graduate in Chemistry, biochemistry or physiology. The appointment is for one year with a possibility of renewal.

Further information may be obtained by writing to the Principal Biochemist or telephoning Romford 46090. Applications, quoting Ref. 25/103, to the Group Secretary, Romford H.M.C. at the Hospital. (222)

#### UNIVERSITY OF ABERDEEN DEPARTMENT OF CHEMICAL PATHOLOGY

Applications are invited for the post of **ASSISTANT LECTURER**. Candidates should have a good honours science degree, preferably in Biochemistry, and postgraduate research experience, though not essential, would be an advantage. Salary on scale: £1,105 to £1,340, with placing according to qualifications and experience. Superannuation (F.S.S.U.) and removal allowance.

Further particulars should be obtained from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by September 30, 1967. (313)

#### MEDICAL RESEARCH COUNCIL

A **HEAD TECHNICIAN** is required for the Laboratory of Cytopathology at the National Institute for Medical Research, to be responsible for supervision and training of technical staff providing an Institute histological service. The department also includes electron microscopical and photographic facilities. Applicants should have wide experience in the techniques of normal or pathological histology, and should preferably possess F.I.M.L.T. or equivalent qualifications. Grade and salary on appointment will be according to age, experience and qualifications on the Senior Technician II scale, range £1,208 to £1,802, with good prospects of promotion to higher grades with a maximum of £2,109.

Applications, in writing, to: Personnel Officer, National Institute for Medical Research, Mill Hill, London, N.W.7. (293)

#### UNIVERSITY OF LEICESTER DEPARTMENT OF GENETICS

A vacancy exists in this Department for a **Technician**. O.N.C. or equivalent qualification required, some experience of bacteriology desirable. Salary from £683 to £968 according to qualifications. Appointment to be taken up in October 1967.

Application to Professor R. H. Pritchard. (298)

# gas chromatography

A CHEMIST is required for the Gas Chromatography Section of the BP Chemicals (U.K.) Limited Research Department, Epsom. His main responsibilities will be the development of on-stream methods of analysis in research and the interpretation of gas-chromatograms by computer. A small laboratory for the experimental work has already been established.

The post requires a knowledge of the principles of gas-chromatography, an interest in instrumentation and an understanding of computer programming. Experience in all three is desirable but training can be arranged, if necessary. Candidates must hold a good honours degree or an equivalent qualification; experience of academic or industrial research would be an advantage but is not essential.

Please write briefly, quoting Ref. No. 739N, to:

Staff Manager,

BP Chemicals (U.K.) Limited, 21-22, Bolton St., London, W.1

(304)

## NEW ZEALAND

University of Canterbury  
Christchurch

Applications are invited for the following appointments, closing on the dates shown:

**READER IN ELECTRICAL ENGINEERING:** Candidates should have a background of research preferably in SOLID STATE CIRCUITS and the application of solid state devices in electrical systems (August 21).

**SENIOR LECTURER OR LECTURER IN ELECTRICAL ENGINEERING:** Candidates should be Honours graduates and preferably have research or industrial experience in one of the following areas: High-speed Data Processing; Systems Engineering, in particular Radar and Sensor Systems; Pattern recognition (August 21).

**ASSISTANT LECTURER IN ZOOLOGY:** Preference will be given to a candidate with qualifications to undertake teaching and research in one of the following fields: Physiology, with special reference to Cellular Biology; Population Genetics (August 21).

**SENIOR LECTURER OR LECTURER IN CHEMISTRY:** Applicants should be organic chemists, and preference will be given to those with special interests in some field of biological chemistry (September 30).

Salary scales: (\$NZ2=£1) Reader, between \$NZ5,600 and \$NZ6,600 per annum; Senior Lecturer or Lecturer, \$NZ3,000 to \$NZ5,400 per annum subject to a bar at \$NZ4,400 per annum. Commencing salary is in accordance with qualifications and experience. (The designation "Senior Lecturer" is used to denote members of staff who are at present above the \$4,400 bar.)

Approved fares to Christchurch will be allowed for an appointee and his dependent family, together with actual removal expenses within specified limits.

Further particulars and information as to the method of application should be obtained from the Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1. (320)

## UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF APPLIED MATHEMATICS  
AND MATHEMATICAL PHYSICS

Applications are invited from candidates with a good honours degree in Mathematics or Physics for a RESEARCH ASSISTANTSHIP in the above Department. The successful candidate will carry out theoretical research, which could lead to the degree of Ph.D. on "The Effects of High Electric Fields of Semiconductors." The appointment will commence on October 1, 1967, and will be tenable for three years at a starting salary of £650 with annual increments of £50.

Applications (three copies), including the names of two referees, should be submitted as soon as possible to Dr. Alan R. Beattie, Department of Applied Mathematics and Mathematical Physics, University College, Cardiff, from whom further particulars may be obtained. (344)

## food research & development

A new major laboratory unit will shortly be opened at the Ranks Hovis McDougall Research & Development Centre at **HIGH WYCOMBE** which will result in greatly enlarged research facilities for the Group. The existing departments of microbiology and cereal research will be considerably expanded and Assistant Heads of these departments are required. They will be expected to initiate, organise, and participate in important research projects.

The **MICROBIOLOGIST** should have a good degree in microbiology or biochemistry and preferably some research experience in the food industry. Age 26 to 36.

For the **CEREAL RESEARCH** appointment, an honours degree in chemistry or biochemistry and practical experience of protein research or enzyme chemistry are necessary; a post-graduate qualification would be useful. Age 26 to 36.

Both these appointments offer good reward in terms of salary and benefits, and the working conditions and facilities for research at the laboratories are exceptional.

Please write with details of age, qualifications, and career to:

The Research Manager,

**RANKS HOVIS McDUGALL (Research) LTD.**

Cressex Laboratories,

Lincoln Road, High Wycombe, Bucks

(325)

## TECHNICAL LIBRARIAN

required by City Overseas Mining Group to be responsible for day to day library routine, including classification and cataloguing. Applicant preferably 25/30 should be qualified librarian; some scientific and/or technical background would be an advantage. Permanent and pensionable position. Salary £850 to £950 (plus bonuses) according to age, qualifications and experience.

Apply in writing, giving full details to Box 584, c/o Walter Skinner, Ltd., Vintry House, Queen Street Place, London, E.C.4. (311)

## THE CHEMICAL SOCIETY

### EDITORIAL ASSISTANTS

Several Editorial Assistants are urgently required for various duties with the Society's scientific publications. A good degree in chemistry is essential and for some duties a working knowledge of languages would be an asset.

Further particulars may be obtained from the Editor, The Chemical Society, Burlington House, London, W.1, to whom applications should be forwarded not later than August 10, 1967. (300)

## UNIVERSITY OF GLASGOW

## CHAIR OF PHARMACOLOGY

Applications are invited for appointment to the Chair of Pharmacology. This is a new Chair in the Faculties of Medicine and Science.

Applications (20 copies) should be submitted not later than August 11, 1967, to the undersigned, from whom further particulars may be obtained.

ROBT. T. HUTCHESON,  
Secretary of the University Court.  
(260)

INSTITUTE OF OPHTHALMOLOGY  
(UNIVERSITY OF LONDON), JUDD STREET  
W.C.1

Applications are invited for the post of ASSISTANT LECTURER for research on the effect of lasers on the eye. Applicants should hold a degree in biology and physiology. Salary in the scale £1,105 to £1,340 per annum, together with £60 London Allowance.

Applications in writing, together with the names and addresses of two referees, to the Secretary at the above address by July 31, 1967. (254)

ROTHAMSTED EXPERIMENTAL  
STATION

## HARPENDEN, HERTFORDSHIRE

## HEAD OF STATISTICS DEPARTMENT

Applications are invited for the Headship of the Statistics Department from April 1, 1968, when Dr. F. Yates, F.R.S., retires. In addition to developing statistical techniques, the department provides a service to various research organizations.

Applications, detailing experience and naming two referees, by October 21, 1967, to the Secretary, from whom further particulars can be obtained. (340)

UNIVERSITY CHEMICAL  
LABORATORY  
CAMBRIDGE

## HIGHER TECHNICAL ASSISTANT

There is a vacancy in the crystallography group for an assistant with sound electronics experience and interest in research to assist with the maintenance and operation of advanced X-ray diffraction equipment and the work of the group generally. Salary scale: £1,024 to £1,417. (287)

HOSIERY AND ALLIED TRADES  
RESEARCH ASSOCIATION

A vacancy exists for a **Research Chemist**, initially to investigate mainly nylon dye adsorption problems. The post is suitable for someone with a B.Sc. Special or Honours degree in Chemistry or Colour Chemistry or an equivalent qualification. Previous experience desirable but not essential. The appointment will be in the Research Officer grade and opportunities exist for promotion to higher grades. Starting salary will be commensurate with experience within the range £900 to £1,600. The post is eligible for F.S.S.U., publication of work is encouraged, and the Laboratories are in pleasant surroundings within easy reach of the City centre.

Applications containing details of age, experience and training should be submitted to the Secretary, 7 Gregory Boulevard, Nottingham. (353)

UNIVERSITY OF  
NEWCASTLE UPON TYNE  
DEPARTMENT OF PSYCHOLOGY

The University invites applications for the post of Research Assistant in the Department of Psychology. Candidates should hold a good honours degree in psychology or a related subject. The Department has good facilities for research and registration for a higher degree is likely to be possible. The person appointed will be expected to undertake some tutorial or demonstration work. The post is tenable from October 1, 1967. The salary will be at an appropriate point within the range of £1,105 to £1,340. Membership of F.S.S.U. is required.

Further particulars may be obtained from the Registrar, the University, Newcastle upon Tyne 2, with whom applications (three copies), together with the names and addresses of two persons to whom reference may be made, should be lodged not later than August 15, 1967. (291)

City of Liverpool  
Education CommitteeLIVERPOOL REGIONAL  
COLLEGE OF TECHNOLOGY

Byrom Street, Liverpool 3.

## School of Pharmacy

SENIOR LECTURER  
IN PHYSICAL PHARMACY

Applications are invited from honours graduates for the above post. Candidates, who should possess a higher degree, will be required to teach to honours degree level, initiate and direct research and promote postgraduate courses. Preference will be given to candidates possessing experience in Surface Chemistry.

## SALARY

£2,140 to £2,380 per annum

Further details and forms of application, returnable to the Principal by August 7, 1967, can be obtained from the Director of Education, Education Offices, 14, Sir Thomas Street, Liverpool 1, on receipt of an addressed foolscap envelope.

THOMAS ALKER,  
Town Clerk.  
(360)

## UNIVERSITY OF BRISTOL

Applications are invited for the post of LECTURER or ASSISTANT LECTURER in APPLIED MATHEMATICS within the Department of Mathematics tenable from October 1, 1967, or as soon after this date as possible. Salary scales: Lecturer, £1,470 to £2,630; Assistant Lecturer, £1,105 to £1,340 per annum with superannuation benefits.

Further particulars may be obtained from the Registrar, the University, Senate House, Bristol, 2, to whom applications should be sent by August 31, 1967. (316)

UNIVERSITY COLLEGE LONDON requires **Research Assistant** in Department of Botany (Professor D. Lewis) from October 1, 1967. Salary, according to qualifications and experience, not less than £850 per annum. Candidates should have degree in Botany, Biochemistry, Microbiology or Genetics, and special interest in biochemical genetics, particularly enzymology.—Applications by August 11 to Secretary, University College London, Gower Street, W.C.1, from whom further particulars may be obtained (ref. 14). (302)

**TECHNICIAN REQUIRED SEPTEMBER** for teaching unit. Sound knowledge of volumetric analysis essential; experience in biochemical techniques an advantage. Salary on scale £577 to £973 according to age and qualifications.—Written applications with names of two referees to Administrator, Department of Biochemistry, South Parks Road, Oxford. (286)

**RESEARCH ASSISTANTS. RECENT B.S. or M.S. or equivalent.** Organic Separation Chemistry, Basic Chemistry, Immunology or Electronics. Salary commensurate with experience and ability.—Apply, J. R. Mitchell, New England Institute for Medical Research, P.O. Box 308, Ridgefield, Connecticut, U.S.A. (352)

## Technicians

I.M.L.T. qualifications or H.N.C. (Applied Biology) for Bio-Chemical, Bacteriological, Haematological, Histological, virological posts in hospitals, industry, and research.—Miss J. R. Horton, G.K. Bureau Ltd., 196 Oxford Street, W.1. MUS 6858. (351)

## UNIVERSITY OF BELFAST

DEPARTMENT OF PURE AND APPLIED  
PHYSICS(SCHOOL OF PHYSICS AND APPLIED  
MATHEMATICS)S.R.C. POST DOCTORAL  
RESEARCH FELLOWSHIP

Applications are invited for the post of Research Fellow which will be tenable from October 1, 1967, or a mutually agreeable later date until September 30, 1971. The Fellow will take an active and responsible part in a new research programme, supported by substantial S.R.C. grants, to measure heavy particle collision cross sections in the thermal energy range from 0.5 eV to 10 eV using crossed beams and pulsed nozzle sources. Candidates should have considerable experimental experience in either physical gas dynamics including shock tube research, atom and molecular beams, measurements of collision cross-sections, or ion detection and analysis systems. Salary will be in the range £1,470 to £2,010 with F.S.S.U.

Applications, including a curriculum vitae and the names of two referees, should be forwarded to Dr. R. M. Hobson, Department of Pure and Applied Physics, before August 14, 1967. (365)

PORTSMOUTH COLLEGE OF  
TECHNOLOGY

## DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited for the post of **RESEARCH ASSISTANT in PLANT PHYSIOLOGY/BIOCHEMISTRY** tenable from September, 1967. The Assistant will be required to investigate the effect of leaf maturity on photosynthetic activity. Applicants should have an honours degree and will have the opportunity to register for a higher degree. Salary scale £950 to £1,050.

Further particulars may be obtained from the Registrar, Staff Office, Portsmouth College of Technology, Hampshire Terrace, Portsmouth, to whom application forms should be forwarded by Friday, August 11, 1967. (364)

## ROWETT RESEARCH INSTITUTE

## BUCKSBURN, ABERDEEN

## MICROBIOLOGY DEPARTMENT

Applications are invited for a post on the **Scientific Officer/Senior Scientific Officer** scale. The post is concerned with extension of work on the nitrogen metabolism of micro-organisms in rumen contents using stable isotopes of N and <sup>14</sup>C and <sup>3</sup>H. Applicants should have a degree in microbiology or in biochemistry or chemistry with experience in microbiology. Salary according to experience within the range S.O. £926 to £1,574 or S.S.O. £1,744 to £2,155. Superannuation under F.S.S.U. Further particulars are available.

Applications, including the names of three referees, should be lodged with the Secretary of the Institute within one month. (329)

**MANCHESTER REGIONAL HOSPITAL BOARD** have a vacancy for a male or female **Scientific Officer** in the laboratories of the **BLOOD TRANSFUSION SERVICE**. An Honours degree in science, pharmacy or biology is essential. Salary £963 (first- or second-class Honours) rising to £1,658, though candidates with postgraduate qualifications or experience may be given a higher starting salary.—Applications should be sent to the Director, Regional Blood Transfusion Centre, Roby Street, Manchester, 1, from whom further particulars may be obtained. (357)

**BIOCHEMIST, PREFERABLY POST-doctoral**, wanted to work on physical and chemical properties of the proteins of the lens, with reference to formation of lens opacities. Salary on scale £1,100 to £1,550 per annum, plus F.S.S.U.—Further information from and applications to Dr. A. Pirie, Nuffield Laboratory of Ophthalmology, Walton Street, Oxford. (356)

**TECHNICIAN REQUIRED TO ASSIST** with research programme in steroid unit. Laboratories in West London Hospital. Whitley Council salary and conditions of service.—Apply: Professor N. F. Morris, Charing Cross Hospital Medical School, London, W.C.2. (295)

## THE QUIET SUN

THE programme of international collaboration in geophysics under the general rubric of the International Years of the Quiet Sun (IQSY, pronounced *iksee* by common tacit consent) has been something of a success, at least if the round-up assembly in London last week is anything to go by. Not merely were the proceedings attended by more people than the organizers had expected—that is not by itself a proof of quality—the assembly itself seems to have been stimulating, and therefore worthwhile in its own right. At the same time it is clear that the machinery of collaboration has been a spur to many people. To make the least of it, a great many people have been stimulated to make useful observations by the knowledge that others are likely to be doing the same things at the same time. And, of course, there are few who receive a telegram saying SOLACTIVITY EXISTS and yet decline at least to look up into the sky. In other words, the IQSY has turned out to be much more real than the pale imitation of the IGY which many people feared would emerge from the proposals first designed in the early sixties.

The IQSY assembly was particularly valuable in showing how new techniques have made possible exceedingly penetrating programmes of research. The studies which have been made of the Sun during the last minimum of the sunspot cycle (in 1964) and afterwards are striking examples of what has been done. There is, for example, the development of birefringent but tunable filters which make it possible to photograph the Sun in chosen spectral ranges no wider than  $0.25 \text{ \AA}$  within several Angstroms of the centre of the Lyman-alpha radiation. The same period has also seen the development of instruments for recording solar X-rays, and enough is now known about the pattern and even the mechanism of microwave radiation from the Sun for the details of particular outbursts of radio waves to be interpreted in terms of the movement of plasma upwards through the atmosphere of the Sun. The fact that sunspots themselves are still more easily described than understood is not a black mark against the IQSY; everybody knows, now at any rate, that it will be several years before the intricacies of sunspots are properly understood.

The abundance of these and other questions is by itself a sufficient proof that the IQSY should somehow continue even though the Sun is no longer quiet. But in what way? And what should be the objectives? Issues like these were given a lively airing in London last week, but perhaps the first thing to say is that there is already something like a firm assurance that a good many of the institutions which have become familiar in recent years are already certain to continue. The data centres, perhaps the most valuable parts of the machinery of the IGY and the IQSY, are likely

to continue without change—except possibly for the better. Moscow and Boulder (Colorado) will become central repositories for a vast quarry of information, and several of the less dominant centres are also likely to carry on. In passing, it is significant that this chimes in well with one common pattern of international collaboration in scientific matters in recent years, for it turns out to be easier to persuade governments to match each other's efforts in some common cause than to put money into a common pool. But what is a data centre? The name itself is possibly unfortunate, and suggests the kind of place which absorbs information more easily than it can surrender it. There was some welcome talk in London last week of how the data centres might be fitted out with facilities for research, so that they could digest as well as store, but it is hard to think that the promoters of the IQSY and its potential successors are thinking ambitiously enough in this respect. The real need is that the data centres should somehow help to simplify the management of the literature which has been created by the spurt of activity in geophysics in the past decade. Quite often, a good deal of what is published in the open literature could be consigned directly to the data centres if only there were some recognizable way in which those responsible in the first place for the collection of the data could be given proper recognition for their work. It is also important that the centres should be places equipped to receive visitors as of right for weeks or even months on end, and be able to provide facilities for research and analysis. The ideal would be if the data centres could become so intellectually attractive that they command the respect and the attendance of a great community of geophysicists.

This raises the issue of what kind of organization should continue to superintend international collaboration in geophysics, which in turn hangs on the answer to the question of what kinds of collaboration seem to be profitable. One of the virtues of the assembly in London last week is that the management provided an outline of the kind of programme it would like to pursue in the years between now and the next solar maximum. Although a great many of the practical suggestions which were made have no particular bearing either on the opportunities which exist for collaboration or on the ways in which the impending solar maximum lends urgency to common problems—everybody knows, for example, that the time has now come for attempts to study the solar wind away from the plane of the Ecliptic—there is enough substance in them to show how the Inter-Union Commission on Solar Terrestrial Physics could occupy itself valuably in the next five years in a continuation and an extension of the work of the past decade. It is exceedingly unlikely that the executive committee of ICSU will fail to recognize this case when it comes to consider final

proposals for the solar maximum at its meeting in October. But here, again, the time has probably come to start thinking of institutions, not just of programmes. In particular, there is a great need for some means of keeping the ball rolling from one sunspot maximum to the next. It is also, of course, important that the management should get itself into a position in which it can tactfully discriminate between efficient research proposals and those likely only to repeat earlier investigations—a need which, to be fair, seemed to have been fully recognized in London last week. On these counts as well, it would be prudent to think of devices by means of which beneficent centralization could be encouraged, perhaps by money.

## BRITISH ECONOMY

MR STANLEY BALDWIN helped to win a place for himself in the history books by saying that wherever six economists were gathered together, there would be seven erudite opinions from which to choose. Without attributing to him one iota of clairvoyance more than he deserves, it is a fair guess that he would have been downcast to see how meagre was the harvest of economic innovation in the debate on the British economy on July 24. There was no shortage of economists, but nothing like a convincing remedy for what seems by common consent to be an unpleasant situation. In the circumstances, it is naturally tempting to wonder whether the traditional arguments about the economic condition of countries like the United Kingdom do not leave entirely out of account essential components of the problem. To say this is not to decry the economists or even to suggest that there is some mystical quality in the construction of an economic system which overrides the doctrines of Keynes and his successors. On the contrary, it is entirely possible that some simple economic stratagem might work like magic—a touch of devaluation, perhaps, or import controls. But which of the many possible remedies would it be best in practice to apply? Which diagnoses of the economic discontents which afflict the British economy are the most accurate? As the British economy is managed, it is uncommonly difficult to answer questions like these. The complaint that would have earned Mr Baldwin gratitude as well as renown is that the trouble with economists is that they have too few tests for testing alternative theories. This is what lends a sense of unreality to debates like that in the House of Commons earlier this week. It is like being compelled to stake a fortune on the outcome of a horse race.

The way things are done in Britain, even diagnosis is difficult. Although the bare bones of the present economic troubles are all too plain to see—too great a disparity between imports and exports, too great a labour force with no work to do, and too small a rate of economic growth—the fine details are surprisingly obscure. Why, for example, has the British economy been flying in the face of economic logic in recent

months by sustaining a rapid growth of the import bill at a time at which credit is being restricted and industrial production held down precisely so as to achieve the opposite effect? What kinds of imports are they, anyway? And why are importers so attached to their potential imports that they go to all this trouble to surmount the several potential barriers which have been constructed to keep imports out? Just as people guess at remedies which might be applied, so they guess at reasons why things like this are happening. In reality, of course, it would be much safer to take steps to find out. No manufacturer of washing powder worth his salt would let his sales decline without seeking to discover in exhaustive detail just what is wrong with what he is trying to sell. By now, in any case, the necessary techniques of market research are quite well understood. In the circumstances, it is entirely anomalous that governments should be shy to do the same things in the complicated and therefore treacherous fields in which they must operate. The most urgent need in the management of the British economy may well be the huge battery of social analysis which could help everybody to understand why this great formless system responds in the way it does to the pressures which afflict it constantly. It would be valuable, for example, to know just how and to what extent people's economic habits are affected by taxes, or by shortages of credit at the bank, or even—at times of economic wellbeing—to encouragements to spend.

In terms borrowed from the kinetic theory, this suggests that the management of the British economy would be a good deal easier if there were a microscopic as well as a macroscopic theory of how it functions. At the same time a better understanding of how the behaviour of the whole is determined by the behaviour of the parts of which it is composed would most probably suggest that the parameters which are supposed to characterize the working of the economic system may not be the most suitable or the most illuminating. As things are, it is easy enough to construct examples of how the fashionable statistics do not serve the purposes which are usually attributed to them. The numbers of people unemployed at any time may be, for example, a good measure of the inability of employers to keep unwanted men and women on their books, but they can only be the roughest measure of how efficiently the manpower of the country is deployed. The 17 per cent or so of the GNP being spent on industrial investment is low enough by comparison with what is spent in other countries comparable with Britain, but who is to answer the crucial question of how much of this investment will add to the real productive capacity of the country as a whole? It is just possible, of course, that these resources are being managed wisely, but it is unfortunately equally possible that they are being used merely to replace assets long since worn out. In this and a host of other ways, there are exceedingly fruitful problems which should be tackled by social scientists or people very much like them.

In the long run, a more intimate involvement of social scientists in the foundations of the economy could serve not merely to reach more accurate decisions about the management of the economy but also to suggest a greater wealth of actions which might be taken. It may be something of a triumph that in the debate this week the Chancellor of the Exchequer was able to mention the word "devaluation" in public without pretending that all holders of sterling would turn their money into any other currency on offer, but this is only a modest relaxation. Why does he not also take up in public the arguments one way and the other for the maintenance of sterling as an international currency? And why does not his colleague, Mr Patrick Gordon Walker, take the edge off his fears that people on the margin between poverty and prosperity might be tempted not to work if welfare benefits were too generous by considering the potential advantages of a statutory minimum wage? Indeed, there is a good case for going even further and asking whether the British Government could not create the mobile labour force for which it is always crying out by making payments of actual money to people who change their jobs. Another possibility is that removal expenses might qualify for deduction of income tax, and there is of course a host of other possibilities all equally at odds with the conventions now followed. The difficulty in all this is that, in the absence of a detailed understanding of how the economy functions, the conventions are indispensable. They have become not safeguards but crutches.

## MORE COLLABORATORS

In all the present rash of international projects looking for members and finance, from Cern and its ambitions to build a 300 GeV proton accelerator to the several offshoots of the international unions, it is important that EMBO should not be forgotten. (Given the name, indifference is a more real danger than forgetfulness.) Formally, the organization is now nearly four years old, and for much of that time it has leaned on the Volkswagen Foundation for support. Constitutionally it is a private company registered in Switzerland, and its aims are to foster research in molecular biology in whatever ways seem appropriate and potentially rewarding. There has been a small but imaginative programme of exchange visits between laboratories, and EMBO (which stands for European Molecular Biology Organization) reckons to have been able to act more quickly and informally in assisting research people to spend short periods in other laboratories than their own. But this is only a beginning. The organization is anxious quickly to increase its activities and to enlarge their scope. It would like to be able to finance—or at least to catalyse—long-term appointments; it wants to provide advanced courses, to be able to make research grants and finally to establish a laboratory of its own, with an independent source of funds. But ambitious plans like these are

not easily accommodated within the framework of a private organization. Everybody seems to agree that funds would have to come from governments, and that governments would often be unable to hand over money unconditionally. Yet, as a meeting in Geneva some months ago (see *Nature*, 214, 445; 1967) seems to have determined, this is not a serious stumbling block. Some kind of agreement between European governments and EMBO seems fortunately to be inevitable. The question remaining to be determined is what the agreement shall consist of.

The first thing to be said is that there was no accident in the choice of Geneva as a site for the first confrontation between the organizers and the governments which may eventually support them. (The Government of Israel has been helping for some time.) Obviously the example of Cern is intended as a model and, if it comes to that, Geneva would make a splendid site for the laboratory which EMBO would like to build. It is right to add, however, that EMBO's plans are comparatively modest. Not so long ago, the organizers had calculated that the cost of their ideal programme would come to hardly more than £250,000 a year—roughly three times its rate of spending now.

The laboratory is a bigger undertaking, costing perhaps £2.5 million to build and to equip, and something in excess of £1 million a year to operate. It is no-surprising that governments have been more sympathetic towards the kind of work which EMBO has been doing already, and sceptical about the laboratory and the delegation to EMBO of the duty to make grants for scientific research. The cost is not entirely negligible even when shared out among a dozen governments or more. But there are also fears, mostly unreasonable, that the creation of a centre of excellence on a European scale would simply serve to drain away from existing laboratories people who are scarce to begin with. The fallacy in this is that the laboratories like that which EMBO has in mind quite quickly increase the stock of people working in the field concerned. A more serious problem is that a central laboratory might take too many people away from teaching; some attention should be paid to this problem in the few months which remain before the next confrontation with the governments. On balance, it would make sense if the European governments—those which adhere to Cern and possibly some others as well—could agree to build the laboratory as well as to finance on a continuing basis the kind of work which EMBO has been doing so far.

Providing money for the financing of research projects on a European basis is a more tricky proposition, cheaper though it might well turn out to be. The trouble here, of course, is that a private organization must necessarily be less able than a government to make compromises between such conflicting pressures as the need to finance excellence and the need to help backwardness. In the long run, there would be great benefits in research councils operating on a continental scale, but nobody should be surprised if, for the time being, this particular dream is unfulfilled.

## NEWS AND VIEWS

### Airbus Launched

NOBODY can claim that the negotiations about the European Airbus have been easy. Sometimes they have seemed endless, but when they were finally concluded on July 25 after a further eight hours of talks in Lancaster House, agreement was apparently secure. Mr John Stonehouse, for the Ministry of Technology, announced that the project will go ahead in the autumn. It will be a two engined 300 seater, using the Rolls-Royce RB 207 engine (a condition of British agreement), and will cost £190 million to develop, £130 million for the airframe and £60 million for the engines.

The aeroplane should make its first flight in 1971 and be in service in 1973. Airframe costs will be shared 37.5 per cent each by Britain and France and 25 per cent by Germany, and engine development will be shared 75 per cent by Britain with the remainder equally divided between the other two countries. In concrete terms, Britain will pay £91.25 million, France £53.75 million and Germany £45 million. Clearly Mr Stonehouse was willing to concede a good deal to get the project off the ground, including design leadership for the airframe, which goes to France. To make the project viable, British European Airways, Air France and Lufthansa will have to buy 75 aircraft, so that unit costs are likely to be about £2.5 million. Mr Stonehouse hopes to sell 300 models of the airbus by 1990, and expects at least some of these to go to American airlines. This may be unduly optimistic; airlines in the US are much more interested in three engined aeroplanes with greater range, and several of these are already on the drawing boards of American companies.

### Cern Goes On

UNDETERRED by uncertainties about the 300 GeV proton accelerator, the management of Cern at Geneva is pushing on with schemes for the further development of high energy physics. For one thing, Cern has now signed an agreement with the Soviet Union for a joint programme of research on the 70 GeV proton accelerator which will be completed later this year at the Serpukhov Institute of High Energy Physics, 100 km south of Moscow. The organization has also signed a contract with the French and German governments for the development and construction of a bubble chamber filled with no less than 20 m<sup>3</sup> of liquid hydrogen and intended for use with the existing 28 GeV proton accelerator. It will cost £7 million.

The Russian agreement, valuable in itself, will no doubt be followed by a similar agreement operating in the opposite direction if ever the 300 GeV machine is built in Europe. Negotiations have been under way for 18 months, and the agreement now signed will be valid for five years. Under the terms of the agreement, teams from Cern will be entitled to bid for experimental time on the Serpukhov machine, competing for the privilege before the appropriate laboratory committee with teams of Russian experimentalists. A programme

of counter experiments has already been designed. In return for access to the machine, Cern will provide for the Serpukhov accelerator pieces of equipment concerned with beam manipulation. A device based on a rapidly increasing magnetic field for extracting fast protons from the machine, of a type which has been operating successfully at Geneva for several years, will be a permanent gift. Cern will also supply a beam separator designed to prepare a beam of high-energy kaons, and this will remain on loan to Serpukhov for ten years.

### Less Defence Science

RESEARCH and development financed by the British defence budget is likely to remain at a standstill for the next three years at least. As part of the cost cutting operation announced in a government White Paper on July 18, research and development costs will be reduced by £30 million from the level planned for the year 1970-71. This represents a cut of just over 10 per cent of the intended budget, which can therefore be assumed to have been in the range £290 to £300 million. The budget for 1967-68 is £260 million, so Mr Healey will be holding expenditure at a constant level at least until 1971.

The ministry is not saying where the cuts will be made—indeed it is doubtful whether that has yet been decided. One problem may be that a large slice of the budget is not directly under Mr Healey's control. A sum of almost £245 million, £188 million of it directly concerned with research and development, is paid through the Ministry of Technology vote, although it is included in the global totals for defence expenditure. Most of this sum—£171 million—is for research and development carried out by industry, and only £17.2 million covers work done in the ministry establishments. Thus, although the establishments cost a grand total of £56 million to run, the defence figure includes only £17 million of it. On this basis, the work of the establishments—including the Royal Radar Establishment, the Explosives Research and Development Establishment, and the Royal Aircraft Establishment—is 70 per cent civil and only 30 per cent military. Even this £17 million does not come under Mr Healey's control. Unless Mr Benn himself starts to wield the axe (which is not impossible) the establishments look relatively safe.

The industrial research and development work looks a more likely target, although again it is Mr Benn and not Mr Healey who will have to make the decisions. Of the total research and development figure for the defence budget, aircraft take the lion's share—£107 million, or 41 per cent. Great savings could clearly be made by dropping aircraft projects, or simply by admitting that the swing wing aircraft which Mr Healey was hoping to build with France is now a lost cause. Other projects in this section of the budget include development work on the Spey engined Phantom aircraft, the vertical take off Harrier (P 1127), the Sea King, a helicopter being developed for the Royal Navy, and two experimental hovercraft designed for military purposes. A limited amount of work on the F 111 and the Anglo-French helicopter agreement have also been approved. Guided weapon research this year will cost £53 million and electronics research £27 million.

It is in the scientific work which falls directly under the Ministry of Defence that cuts seem most likely. The Royal Navy, for example, spends a total of £34.6 million on activities classified as research and development. About one-third of this goes on weapon systems and radio and navigation equipment. The Army spends about £21 million, £5 million of it in industry. It supports several research establishments, including the Chemical Defence Experimental Establishment and the Microbiological Research Establishment. Finally, there is the Meteorological Office, costing around £6 million per year, supported by the Royal Air Force.

## Teaching Adults

THE demand for adult education is a "growing and not a diminishing problem", according to Mr Goronwy Roberts, Minister of State at the Department of Education and Science. Mr Roberts was opening a conference at Birkbeck College, London, convened to discuss the problems of the mature student. Mr Roberts encouraged those involved in part-time education in Britain; not only did it help occupational mobility, but it could perhaps do more, and he visualized tired middle-aged executives being revived by the study of Plato and Aristotle. On a more down to earth note, he had some sharp words to say to Colleges of Advanced Technology which had abandoned sandwich courses since becoming universities. "We are not, I hope, going to lose the sandwich courses," he said, making a hope sound more like a challenge.

The address at the opening ceremony was given by Dr F. Cyril James, Principal Emeritus of McGill University, Montreal. Why, asked Dr James, was there still a need for part-time education, when government grants were available for most able students to take full-time courses? He gave four reasons; the need for higher degrees, supplying deeper and more specialized knowledge; the need for regular retraining; the changing pattern of employment—"something like half the working population are today working at jobs that did not exist at the opening of the twentieth century"—and finally, the fact that more than half the children in Britain give up full-time education as soon as they can, at the age of 15. Part-time students did have different problems from regular ones, he thought; they needed libraries and laboratories open until a late hour every night of the week, and on Saturdays and Sundays. Correspondence courses and a proper use of television as an educational medium could also help.

During the conference itself, Mr G. O. Arlt, President of the Council of Graduate Schools in the United States, gave details of the numbers of graduate part-time students in America. Despite difficulties of definition, which make it possible for the Ivy League universities to deny that they have any part-time students at all, while the California State Colleges, anxious to document their services to the community, claim 28,738 part-time and only 5,536 full-time students, the US Office of Education reported in 1965 a total of 477,535 graduate students, of whom 280,714 (59 per cent) were part-time. The wastage among part-time students is worse than that among full-timers—"There appears to be a staggering attrition rate, probably as high as 60 per cent . . . but no matter how you look at

it, part-time graduate study is with us to stay, and universities may as well abandon their futile efforts to exorcise the phenomenon." Other delegates might have put the case for part-time study in more enthusiastic terms, but probably agreed with the conclusion.

## Nice Work if You Can Get It

RARELY can a House of Commons committee have produced a more scathing report than that published last week by the Committee of Public Accounts. It was investigating the case in which Bristol Siddeley Engines had overcharged the Ministry of Aviation (later Technology) for work done on the overhaul of Sapphire and Viper engines between 1959 and 1963, costing a total of £16.5 million. In March this year the company finally agreed to repay to the ministry £3.96 million, which includes an unspecified figure (about £400,000) for accidental double charging.

The committee's description of how the situation came about makes fascinating reading. In the end, nobody emerges with reputation unscathed—even the final settlement is criticized. A separate contract was placed each year, on a "price to be agreed" basis, for the stripping, inspection, reassembly and testing of each engine. In many cases the final price was not settled until a major part of the work had already been done, so that the company must have had a very firm idea of costs. Under the contract system, however, it was not obliged to reveal these to the ministry. After the Ferranti affair, in which Ferranti, Ltd., agreed to repay £4.25 million excess profits made under the contract to produce the Bloodhound missile, the ministry seems to have smelt a rat. It asked BSE for costs incurred on past contracts, which were refused; BSE did admit, however, that reductions in prices for 1963-64 and 1964-65 might be necessary, and submitted new quotations which seem merely to have encouraged the ministry to probe further.

Much of the ethical weight of argument in the report hangs on what is meant by the "fair and reasonable" prices to which both the ministry and the company were contractually committed. The company argued that a total view of its government contracts should be taken, and that on this view it was not overcharging. The ministry, and the committee, did not accept this view. "Government support . . . can be properly given only by way of conscious decision . . . and not by submitting to overcharging, of which the government is unaware, on quite different contracts." On some contracts the profit on costs amounted to more than 150 per cent, and the average figure over the four years was 74 per cent.

The ministry is also blamed by the committee. Its performance "fell far short of an acceptable standard". Even after the discovery by the ministry of the size of the overcharging, things seem to have moved at a leisurely pace, with gaps of up to a month between letters from the ministry and replies from the company. The final settlement was reached quite quickly after a letter in which is recorded Mr John Stonehouse's view that it was "the most disturbing case he had come across in the whole of his public life". Even the final settlement gets its share of criticism; in the Ferranti case, the final settlement left the company with profits of 21.4 per cent on costs, although the contract had involved a new project with consequent risks. The

BSE repair contracts involved virtually no risk at all, and yet the company has been left with a retained profit of 32 per cent on costs. Not surprisingly, the committee was dissatisfied with this. It also recommended a review of the spare parts contracts entered into in the same period. Mr Wedgwood Benn, Minister of Technology, who could hardly do nothing about a report so critical of his ministry, agreed on July 25 to undertake this review, but declined to reopen the profits inquiry.

## No Redundant Geophysicists

THE future for international geophysical co-operation seems likely to be one of consistent, if more modest, progress than in the past. This has emerged from the meeting of the Committee on Space Research which has been going on in London over the past week. Dr Herbert Friedman, President of the Inter-Union Commission on Solar Terrestrial Physics—which is likely to be charged with the responsibility of maintaining the international programmes—said last week, “The IGY and the IQSY were special efforts—there is no need to generate special efforts now. The problem is to keep programmes up on a continuing basis; we must keep momentum up as long as possible.” The inter-union commission consists of Dr Friedman, twelve representatives from different scientific disciplines and representatives from various organizations, including the World Meteorological Organization, the Scientific Committee on Antarctic Research (SCAR), the Scientific Committee on Oceanic Research (SCOR) and the Federation of Astronomical and Geophysical Services (FAGS). “This is a continuing field, and therefore the commission will continue indefinitely,” Dr Friedman added. It would not, he said, be a stop-go operation.

At least two of the data centres set up for the IGY and IQSY will remain in existence. These are the *A* and *B* centres in Moscow and Boulder, Colorado. There is also a good chance that a number of the *C* centres will be kept in operation, although this presumably depends on the attitude of the governments supporting them. The *C* centre at the Radio and Space Research Station at Slough will be one that will keep going. Both Dr Friedman and Professor W. J. G. Beynon, chairman of the organizing committee of the IQSY, were optimistic about the international reaction to collaborative projects. In developed countries there is no objection, and underdeveloped countries see the projects as an entry ticket to big science. “The motivation is strong to see the programmes continue,” Dr Friedman observed.

There is likely, though, to be a change in the emphasis of the programmes. More discriminating experiments are likely to take over from what Dr Friedman described as the “shot-gun” approach adopted so far. He suggested that simultaneous measurements at different points in space—one either side of an auroral curtain, for instance—could provide much useful information. Although synoptic measurements would be continued, they might well start to concentrate on the inhomogeneities in the atmosphere and the fine scale detail of the ionosphere. The data centres themselves, Dr Friedman hoped, could initiate research on data handling, rather than being merely passive recipients of data.

## Going to University

THE regulations which determine whether young people can get into a British university in 1968 differ most obviously from those now current in their greater bulk. But the *Compendium of University Entrance Requirements* (published by the Association of Commonwealth Universities for the Committee of Vice-Chancellors and to be had from Percy Lund, Humphries and Co., 14s. 6d.) is also a slightly more liberal document in that there is now a more obvious sprinkling of university departments which do not rigorously specify in advance the qualifications which potential entrants must somehow attain. In a foreword to the document, however, Sir Robert Aitken, Chairman of the Standing Conference on University Entrance, and Sir Charles Wilson, Chairman of the Committee of Vice-Chancellors, promise better things for the succeeding year 1969–70. For by now it is an open secret that the vice-chancellors have been working hard on a document intended to clothe with flesh the bare bones of the policy enunciated several years ago which would have the effect of allowing intending entrants to universities to do so without having spent virtually all their time as seniors at school working on the courses they will later follow at university.

## New Zealand Brain Drain

NEW ZEALAND'S loss of about 40 per cent of a year's output of first class honours graduates each year to the brain drain makes Britain's loss of about 15 to 20 per cent of all PhD graduates look small. In the New Zealand National Research Advisory Council publication, *Some Aspects of Technical Manpower in New Zealand*, it is estimated that the permanent loss amounts to 67 per cent of first class honours physicists, 48 per cent of first class honours mathematicians, and 35 per cent of first class honours chemists and geologists. New Zealand also loses about 25 per cent of those with a lower level of honours degree. New Zealand's total output of masters and bachelors graduates from 1960 to 1964 was 663, of whom 242 were first class graduates. In these years there was a total output of 199 chemists, 63 first class honours; 131 mathematicians, 48 first class honours; 102 physicists, 36 first class honours; 69 zoologists, 34 first class honours; 55 geologists, 15 first class honours; 42 agricultural scientists, 16 first class honours; and 35 botanists, 15 first class honours.

The report says that according to the Government Statistician, New Zealand gains more scientists than it loses, though it in no way confirms the figure. The main problem is the quality and research interests of those gained and lost rather than their total number. A striking feature of the figures is that there is a comparatively small loss in botanists (4 per cent), agricultural scientists (19 per cent) and zoologists (24 per cent), which confirms that those sciences with strong local links more easily retain good graduates than those which are more independent of the environment.

The report suggests that there is a need to arouse interest in all students in all disciplines in research problems peculiar to New Zealand. While this may require more conscious effort in disciplines such as mathematics and physics than in zoology, for example, it is suggested that this is not impossible. This is, in

fact, one of the declared purposes of the postgraduate scholarship scheme of the New Zealand University Grants Committee.

## In the Steps of Rutherford

THE New Zealand National Research Advisory Council's estimates for expenditure on scientific research slowly increase, both absolutely and as a percentage of the gross national product. The estimate for 1966-67 is just over £10 million or 0.5 per cent of the gross national product. When this is compared with the British figure of about 2.6 per cent of the gross national product or the American figure of about 3 per cent, it is perhaps not surprising that New Zealand loses such a large percentage of first class graduates in the brain drain. The Council recommends that the Government should return to its support of the policy the Council originally set out in its first annual report, that of a steady and deliberate growth in the research effort with growth rates concentrated in those areas of research most likely to prove beneficial to the country's economy.

The Council recommends the expansion of the laboratory building programme if present urgent needs are to be met and if expansion of certain research is to be carried out. It points out that accommodation is already overcrowded and that, although it is estimated that the building requirements for the Department of Scientific and Industrial Research would involve £5 million over the next five years (excluding the cost of land), the annual expenditure over the past two years for land and building for scientific purposes for all Government Departments has amounted to only £0.5 million.

The chief new recommendation of the Council is that a programme of ecological research should be implemented by the Government. Less than one-third of New Zealand is intensively farmed and a large proportion of the remainder is composed of forest and country tussock grassland, forming important water catchment areas. Problems of soil erosion which might lead to flooding have pointed the way to urgent changes in the basis of land usage. Recently there has been a realization that water resources, long regarded as unlimited, need prudent management.

## Discussing Proteins

THE Chemical Society has found enthusiasm for its proposal to form a Protein Group. The idea is to bring together scientists from different disciplines who share an interest in proteins and peptides. Discussion would cover the synthesis, structure, physical properties and biological activity of proteins, and organization of the meetings would be provided by the Chemical Society. Dr G. T. Young, of the Dyson Perrins Laboratory at Oxford, to whom interested scientists have been asked to write, reports an encouraging response—about 50 have replied approving the idea. Membership of the group would not be confined to members of the Chemical Society, but in order to get it started it is necessary to provide evidence that at least 25 fellows are interested. The idea can then be put forward to the Council of the Chemical Society.

The next step will be to organize an inaugural meeting, some time before the end of the year. This would probably be a scientific meeting, to encourage as many

as possible to come. It would also be necessary to elect a committee, but Dr Young modestly declares that he has no ambitions in this direction. He is hoping that the group will attract the younger workers, and that they will be prepared to run it. "We don't want the same old people giving the same old papers," he says.

## Extending Photography

THE year 1967 could be a vintage year for the Loch Ness monster. Earlier this year it was announced that the Highland and Islands Development Board had given a grant of £1,000 to a "Monster" study group, headed by Mr David James, and on July 20 Kodak Ltd. announced that it was giving £1,230 to an insurance underwriter, Mr T. K. Dinsdale, to carry out his own studies into the phenomenon. This sudden largesse in the direction of Mr Dinsdale is all part of the Kodak Awards for 1967-68. The purpose of these awards is to stimulate original thought on problems relating to the photographic process and to extend the use of photography into other fields. Kodak has made seventeen awards this year totalling £9,433. The research supported ranges from Mr Dinsdale's project to medical photography, and includes a large number of studies of audio-visual aids in teaching.

Another project is that of Dr W. Hartson, who is studying techniques for producing photomicrographs of the smallest blood vessels in normal and diseased skin using intense infra-red light and infra-red sensitive film. Mr C. C. Gilson, a medical photographer, will investigate various methods of making contour maps of the human cornea using interferometry. His purpose is to detect damage to the cornea caused by wearing contact lenses; the established method, called keratography, is apparently not sufficiently accurate.

The awards are given to individuals rather than institutes. They are given not only to professional researchers but also to people such as schoolteachers who wish to study the uses of photography in their vocation.

## Radiation and the Immune Response

from a Correspondent

RADIATION and the control of the immune response was the topic discussed at a meeting organized by the International Atomic Energy Agency and the French Atomic Energy Commission, which was held in June this year at the Fondation Curie in Paris.

The nineteen delegates heard persuasive evidence for a radiosensitive antigen-processing step inside macrophages which might play a significant part in the immune response. Immunological tolerance can be induced in newborn rats by extremely low doses of salmonella flagellin antigen which, when labelled, cannot be detected by electron microscopy. Thus, the determination of a tolerance-inducing threshold for purified histo-compatibility antigens in man may be a practical proposition.

A suggestion that in the evolution of the immune response the antibodies appear in the sequence IgM, IgA, IgG contrasted with the evidence for the affinity of antibodies for monovalent haptens, which is in the reverse order. Memory was excellent for IgG, but less impressive for IgM and IgA. Evidence seems to sug-

gest that different cells produce antibodies of different affinities but that the immunoglobulins produced by one cell are homogeneous. No immunoglobulin class disappears completely after whole body irradiation of mice; amino-acid incorporation has shown that one day after 950 rads all classes are produced. A primary immune response has been induced in an entirely *in vitro* system, which seems to favour the view that lymphoid cells are multipotent and can form antibody without division when forced to do so.

In thymectomized X-irradiated mice, grafted with a thymus and with restored bone-marrow, two populations of cells have undergone mitosis after antigenic stimulation; these were cells derived from thymus and bone-marrow respectively. In animals thymectomized, but not grafted with a thymus, no detectable antibody has been found nor has antigenic stimulation caused an initial mitotic increase, which is further evidence that cells of thymic origin must divide before a population of cells from bone-marrow can proliferate and go on to form antibody. It has been confirmed that cells from bone-marrow can effectively re-equip the irradiated recipient's immune system only as long as the thymus is present.

Foetal liver is believed to be relatively poor in immuno-competent cells and has been used to restore lethally irradiated rhesus monkeys. Although up to  $10^9$  cells/kg have been injected as therapy, restoration of haematopoietic function has been achieved very rarely. Furthermore, the animals receiving allogeneic foetal cells developed the "secondary radiation syndrome" probably caused by a graft versus host reaction. When bone-marrow was transplanted into supralethally irradiated dogs, the rapid appearance of hyperbasophilic cells in the peripheral blood within a few days of bone-marrow therapy was indicative of a strong graft versus host response. This type of cytological transformation seems to be restricted to the dog. To render bone-marrow cells less likely to cause graft versus host attack, pre-incubation of immuno-competent cells at 37° C has been employed. This reduced the graft versus host response and indicated that the immunological potential of incubated lymph node cells had been reduced.

A substantial proportion of irradiated rats receiving allogeneic bone-marrow cells have developed myelofibrosis, occurring simultaneously with marked haemopoietic activity in the marrow. Part of the aetiology of this syndrome might be a delayed graft versus host rejection phenomenon. Heavily irradiated (10,000–30,000 r.) tissue undergoes a change, as indicated by the second-set like rejection of irradiated isografts.

## Dangerous Life

THE hazards of modern life were discussed last week by the British Academy of Forensic Sciences at its annual scientific meeting held at the Institute of Psychiatry at the Maudsley Hospital. Mr. R. Kell explained how prolonged exposure to noise, which he defined as "sound unwanted by the recipient", can cause deafness. A survey of female jute weavers in Dundee has shown that after twenty years working with the looms, which may produce 100 dB and more—a very loud noise—there is considerable loss of hearing for sounds which have a frequency of around

4,000 cycles/sec. This loss of hearing is not usually noticed until it extends into the frequency range of speech, when the inability to hear sounds of particular frequencies can make speech almost or wholly unintelligible. This is at the moment very difficult to mitigate, because hearing aids which are merely amplifiers of sound cannot help when the ear is unable to respond to certain frequencies. The deafness develops because noise of an intensity greater than about 110 dB can eventually destroy the nerve cells on the basilar membrane in the inner ear, which produce electrical potentials when stimulated by sound of a particular frequency. The ear drum rarely bursts and when it does usually heals up again. Once the nerve cells have been destroyed their particular frequency of sound cannot be heard again.

Loss of hearing is not only an occupational hazard; noisy hobbies such as rifle shooting can have the same effect, and some deafness has been found in pop singers and musicians who play loud instruments such as the bagpipes. Traffic is now the most common source of noise outside factories and the engine rooms of ships.

Discussing the hazards of breathing in the modern world, Dr A. E. J. Eggleton of the AERE, Harwell, described how air pollution by carbon monoxide is increasing as more cars produce more exhaust fumes. The concentration of this gas in Fleet Street on a normal summer day has been found to show two peaks, one at 9.00 a.m. and the other at 6.00 p.m., when the density of traffic is greatest. This is the pollutant the concentration of which on the air comes nearest to the maximum permitted industrial concentration of 100 p.p.m., and 200–300 p.p.m. have been recorded in busy streets. Other dangerous pollutants include smoke, sulphur dioxide, oxides of nitrogen and carcinogenic hydrocarbons, although in most cases it is very difficult to correlate their concentrations in the air with mortality and morbidity.

## Molecules Constrained

from our Correspondent in Thermodynamics

AN exceedingly elegant demonstration of how to calculate the thermodynamic properties of an assembly of polymer molecules each of which is subjected to some topological constraint has been provided by Professor S. F. Edwards of the University of Manchester in the current issue of the *Proceedings of the Physical Society* (91, 513; 1967). Elegance apart, the calculation will be of great interest to those concerned to account for the properties of materials such as rubber or glass, usually in terms of chemical linkages between different molecules. Edwards's analysis suggests that the properties of polymer molecules lumped together in bulk may be at least in part explicable by the fact that molecules in such assemblages are inevitably subjected to topological constraints of various kinds. It remains to be seen whether the simple calculations which he has now provided will prove capable of generalization to more realistic models, but there is at least some room for improvement.

In the simplest model of a constrained assemblage, identical molecules are supposed free to move in two dimensions and each of them is fixed at the ends to two fixed points. A constraint is provided by supposing that the end of an impenetrable rod is placed on

the plane among the loosely looped molecules. The effect of this constraint is permanently to separate the molecules into several different categories—there are those which lie entirely on one side of the rod, those which lie entirely on the other, and those which are looped about the rod once, twice and several times. But each molecule is a kind of random walk with fixed end points and a definite number of paces. For the simple two-dimensional problem, Edwards shows how it is possible to calculate the probability that a random walk will generate analogues of the molecules in the several distinct topological classes, which is something of a triumph in itself. Each probability, of course, is a function of the end points of the molecules and of the point at which the rod-like constraint is made to intervene. It is no surprise that the entropy of the system as a whole turns out to differ from that of an unconstrained system by the addition of terms of the form  $NkP \log P$ , where  $P$  is the probability that a random walk will yield molecules in a certain topological class and where there is one term for each class.

The great interest of the calculation is that it provides a general expression for the entropy of a constrained system in which the parameters of the constraint enter explicitly. On paper, at least, it is possible to calculate mechanical properties such as elastic constants. Edwards himself points out that the two-dimensional problem is unrealistic, that the three-dimensional analogue is that of an assemblage of molecules threaded in various ways through a closed loop and that this is more directly analogous to real situations. The next instalment in his calculation will be worth waiting for.

## Neuropathology at Wye

Professor C. W. M. Adams writes :

THE second symposium on neuropathology, organized by N. T. Blau and Helen Payling Wright, took place at Wye College from July 10 to 14. The chief purpose of these symposia is to highlight growing points in the neurological sciences. The topics on this occasion were Schwann cells, neuroviruses, immuno-neurology, neurochemistry, developmental neurology and cerebrovascular disease.

Peripheral nerve ultrastructure was lucidly illustrated by D. N. Landon and P. K. Thomas. We learnt that Schwann cell cytoplasm extends into the Schmitt-Lanterman cleft. Discussion also centred on the role of the Schwannian paranodal apparatus and on possible cation-binding by acid mucopolysaccharide in the internodal gap. This last theme was continued by C. J. Duncan, who suggested that the initial component in nerve conduction is mediated by  $\text{Ca}^{++}$ -activated ATPase, whereas the axon potential is propagated by an ion-sensitive protein. J. B. Cavanagh discussed Schwann cell injury: diphtheria toxin inhibits certain of the cell's metabolic activities, whereas X-irradiation impairs its proliferative activity.

The concept of "slow virus" in neurological disease was reviewed by A. P. Waterson, while J. A. Dudgeon showed that viruses persist in tissues for long periods after initial infection. Transmission of virus along Schwann cells appeared, from F. Kingsley Saunders' experimental work, to be a likely route by which an

encephalitis virus enters the brain. Within the brain H. E. Webb concluded that Langkat virus directly attacks neurones, while hypersensitivity is responsible for perivascular inflammation and oedema. The scrapie agent remains as enigmatic as ever; I. H. Pattison wondered whether it might be a relatively simple peptide quite unrelated to virus.

In experimental allergic encephalomyelitis S. Leibowitz reported that grossly increased vascular permeability is associated with perivascular inflammation, even though slight leakage occurs in the absence of local cellular infiltration. He showed that simultaneous injection of anti-lymphocytic serum slows down the immunological reaction, so that true demyelinating lesions appear even in the guinea-pig. D. Hughes illustrated the demyelinating and gliotoxic effect of multiple sclerosis serum. Nevertheless, similar results were obtained in motor neurone disease and in a quarter of control subjects. Continuing the immunological theme, the presence of anti-brain antibody was demonstrated by P. C. Wilkinson in the serum of patients with carcinomatous sensory neuropathy. Antibody to sympathetic nerve growth factor was the subject of E. Zaimis's paper; such immuno-sympathectomy is clearly a valuable tool for studying autonomic functions.

Several fruitful lines of neurochemical research were surveyed. A. N. Davison demonstrated differential incorporation of components into developing myelin and considered that movement of lipoprotein units within the sheath might explain such findings. After this examination of the brain's myelin fraction, V. P. Whittaker surveyed the synaptosome fraction: he showed that acetylcholine is synthesized in synaptic vesicles, whereas cholinesterase activity is sited on the synaptosome's external membrane. Biochemical lesions were next discussed. W. N. Aldridge outlined an elegant method for elucidating the reaction of organophosphorus compounds with certain brain protein fractions. The neurological manifestations of hydroxocobalamin deficiency, Leber's disease and tropical malnutrition were attributed by J. Wilson to different forms of impaired cyanide detoxication.

In the developing tadpole's cord, A. Hughes showed that some 85 per cent of motor cells atrophy; he inferred that such cells fail to make functional peripheral connexions. Turning to the nutritional aspects of brain development, J. Dobbing established that myelin and possibly other elements fail to "catch up" if the grain is undernourished during the early vulnerable period of its development. Concluding this subject, M. Berry and J. T. Eayrs portrayed morphological and behavioural changes after irradiation and hormonal injury to the developing brain.

## Phage Coat Protein

from a Correspondent in Cell Biology

THE entire genome of the closely related RNA bacteriophages R17, f2, MS2 and fr consists of a single stranded RNA molecule with sufficient information to code for about 1,100 amino-acids. This RNA molecule has the dual function of providing a store for the genetic information and also acting as a messenger. Zinder and his co-workers (1966) and Gussin (1966) have shown that the genomes of f2 and R17 have at

least three, and probably only three, cistrons specifying the phage coat protein, an enzyme RNA synthetase to replicate the phage RNA and the so-called "A" protein or maturation factor. Since each phage particle consists of one RNA molecule enclosed in 180 coat protein molecules and one or two molecules of "A" protein, some mechanism must regulate the translation of the genome to ensure that the coat protein cistron is translated much more often than the two other cistrons. Lodish and Zinder (1966) suggested that the coat protein itself acted as a 'repressor'. Sugiyama and Nakada (*Proc. US Nat. Acad. Sci.*, **57**, 1744; 1967), who recently achieved the *in vitro* assembly of phage-like particles from coat protein and phage RNA (*J. Mol. Biol.*, **25**, 455; 1967), have obtained some direct evidence suggesting that coat protein does in fact play a part in this regulation by complexing with the phage RNA.

They compared the *in vitro* incorporation of histidine, phenylalanine and leucine in an *E. coli* cell-free system programmed with MS2 RNA or MS2 RNA that had, by prior incubation with coat protein, been made into Complex I, that is a few coat protein molecules attached to an RNA molecule. Since MS2 coat protein does not contain histidine the incorporation of histidine is taken as a measure of the synthesis of RNA synthetase and "A" protein. Sugiyama and Nakada find that with Complex I as messenger incorporation of histidine is 71-77 per cent less than with MS2 RNA as messenger, whereas phenylalanine incorporation is only inhibited by 19-36 per cent. The incorporation of histidine was also always more strongly inhibited than the incorporation of leucine or alanine. It appears that the coat protein selectively reduces synthesis of non-coat protein. This inhibitory effect is specific; MS2 coat protein does not inhibit protein synthesis directed by TMV RNA or PolyU. Eggen and Nathans (*Fed. Proc.*, **26**, 449; 1967) have briefly reported similar observations to those of Sugiyama and Nakada.

Does the coat protein regulate translation *in vivo* as well as *in vitro*? Two pieces of evidence suggest that it may. First, in MS2 infected *E. coli* the ratio of coat protein to non-coat protein synthesized increases progressively during the infective cycle. Second, as Lodish and Zinder *et al.* (1964) found, amber mutants of f2 that are unable to make coat protein produce large quantities of RNA synthetase; this suggests that coat protein molecules are involved in the normal regulation of RNA synthetase synthesis.

The existence of polar coat amber mutants of f2 and R17 (Zinder *et al.*, 1966; Gussin *et al.*, 1966) indicates that the coat protein cistron precedes the synthetase cistron. Furthermore, the failure to synthesize "A" protein *in vitro* can be interpreted as showing that the "A" cistron is the last of the three. This would make the order of the cistrons coat protein first at the 5' terminus, followed by the RNA synthetase cistron and finally the "A" cistron at the 3' terminus. It may well be that the coat protein when regulating translation attaches to the 3' terminal end of the RNA first and then progressively towards the 5' terminus. If this is so, the "A" cistron will be translated least often and the coat protein cistron most often. This is an attractive hypothesis because we know that although each phage requires 180 coat protein molecules, it needs only a few (and certainly fewer than 10) molecules of "A" protein.

## Parliament in Britain

### Dragon Reactor

To avoid the premature shut-down of the Dragon reactor project at Winfrith Heath, the British Government is prepared to bear most of the cost of the project through 1968. This was announced by Mr Wedgwood Benn, Minister of Technology. The Dragon high temperature reactor is supported by the OECD, and doubts about the future of the project—which is due to run until 1970—have been spreading since the Euratom countries have been unable to agree about the support costs. To finish the project would need another £4.5 million, according to evidence given to the Select Committee on Science and Technology by Sir William Penney. Costs for 1968 may therefore be about £1.5 million. Unless Euratom stops dragging its feet on the project, it may well have to close down, as the British Government is unlikely to do more than a temporary holding operation. (Written reply, July 25.)

### Sonic Bangs

QUESTIONS on sonic bangs were prominent in both Houses. On July 17 in the House of Commons the Minister of Technology, Mr Wedgwood Benn, stated that his Department and others concerned would investigate any reports of adverse effects of sonic booms. His Department also had a programme of scientific research into the nature and effects of sonic bangs. Mr Benn preferred not to anticipate in detail the information which this series would provide about higher intensity tests, but valuable lessons should be learned. In reply to further questions on July 18, Mr Benn said he was aware that there was some concern at the disturbance being caused, but he did not think it justified stopping the exercise, which was planned to end that week. The place and time of the final flight—noon on July 21—would be announced in advance, and all the remaining flights in the series would be designed to hold the bangs to within the same degree of intensity as those that had already been made. Whether or not we built a supersonic airliner, at some stage this country would have to decide whether it was prepared to allow supersonic flying. One of the reasons for the tests, he said, was to see whether people complained about tests that do not take place. Possibly, he suggested, the high and prolonged intensity of an aircraft taking off and landing was more irritating and more likely to affect hospitals and others than the single impact of a supersonic plane.

In the House of Lords, Lord Shackleton said that two isolated instances of momentary fluctuation in the calibration of equipment at Frenchay Hospital had been reported but that the equipment immediately returned to normal and no damage of any kind occurred.

### Veterinary Medicine

MR A. BOTTOMLEY, Minister of Overseas Development, reported that after discussions with Edinburgh University, he intended to provide a grant of up to £210,000 in the five year period up to March 1972 for erecting, furnishing and equipping a building next to the University's existing Veterinary Field Station to provide a Centre for Tropical Veterinary Medicine. An agreement had recently been concluded with the University on the conditions under which the centre would be established and managed.

## Growth and Decay of a Hurricane

*For explanation, see overleaf*

This sequence of pictures (reading down each column in turn) was taken from the stationary weather satellite ATS 1 launched from the United States earlier this year. It shows various stages in the development and decay of a hurricane system over the South Pacific between April 6-15, 1967.

Photographs are taken by the satellite at intervals of roughly 23 minutes.

These pictures are taken from a film prepared by V. E. Suomi, A. F. Hasler and J. Kornfield of the Department of Meteorology, University of Wisconsin.

Shklovsky has suggested that the Scorpius X-ray source is a binary pair and that the X-radiation arises from the collision of material from a giant star with a neutron star. The theoretical complications of such a model are now found not to match actual measurements and it is suggested that the bremsstrahlung effect occurs between a giant star and a white dwarf.

THE blue stellar object which has been identified with the strong Scorpius X-ray source<sup>1</sup> emits about a thousand times as much energy in the X-ray region as in the visible region. It has been suggested<sup>2</sup> that the vibrations of a compact star, with a massive electron degenerate core, may be able to shock-heat a surrounding coronal region which could have these properties. This idea has been tested through a variety of hydrodynamic model calculations<sup>3</sup>, and it has been found that even with over-optimistic assumptions about the parameters, the resulting X-ray emission falls at least two orders of magnitude short of the  $4 \times 10^{36}$  ergs sec<sup>-1</sup> which appears to characterize the Scorpius source.

Shklovsky<sup>4</sup> has suggested that the Scorpius X-ray source is a member of a close binary pair of stars. He proposed that one of the stars is a neutron star and that it is rapidly accreting mass from its companion. Gravitational potential energy released then creates a hot plasma which radiates thin-source bremsstrahlung (collision radiation) in the X-ray region.

In this article we consider some general properties of mass accretion on to a compact star. We then point out some difficulties with Shklovsky's suggestion and suggest an alternative model.

It should first be noted that there is an upper limit to the rate at which mass can accrete on to a star, which results when the outgoing radiation stress on the infalling

material becomes equal to the gravitational stress<sup>5</sup>. This condition is

$$\frac{N_0 \sigma_T}{\mu_e c} \frac{L}{4\pi R^2} = \frac{GM}{R^2} \quad (1)$$

where  $\sigma_T$  is the Thomson scattering cross-section,  $L$  is the luminosity generated by the infalling material,  $N_0$  is the Avogadro number, and  $\mu_e$  is the mean mass per electron. For a star of one solar mass, with  $\mu_e = 4/3$ , the resulting maximal luminosity is  $1.7 \times 10^{38}$  ergs sec<sup>-1</sup>, which is considerably larger than needed to account for the luminosities of X-ray sources. For reasons which will become obvious, we take the total luminosity of the Scorpius source to be at least four times the apparent X-ray luminosity, or about  $1.6 \times 10^{37}$  ergs sec<sup>-1</sup>.

Here we shall investigate the following pattern of events. The infalling material is optically thin and the time required to cool by radiation is long compared with the infall time. When the infall is halted the gravitational potential energy released is converted to gas kinetic energy; the plasma remains optically thin. The temperature characteristic of the resulting thin source bremsstrahlung is estimated. The absorption and re-emission of radiation by the underlying stellar surface are also considered.

When the infalling material is halted, the gravitational potential energy released is converted into gas kinetic

energy. The maximum coronal temperature which thus results is

$$T_c = \frac{2}{3} \frac{GM\mu}{N_0 k R} \quad (2)$$

where  $\mu$  is the mean molecular weight,  $G$  is the gravitational constant,  $M$  is the stellar mass, and we have assumed that the conversion takes place at the stellar radius  $R$ . For a star of one solar mass, with  $\mu = 2/3$

$$T_c = \frac{7 \times 10^{17}}{R}$$

For a neutron star  $R \approx 10^6$  cm and  $T_c \approx 7 \times 10^{11}$  °K. This high temperature indicates that the gas contains relativistic electrons, but corrections for relativistic effects need not be made at the present crude level of our considerations. For a white dwarf we take  $R \approx 2 \times 10^8$  cm, and thus  $T_c \approx 3 \times 10^9$  °K.

It is also possible to estimate the pressure at the coronal level where these high temperatures are produced. The rate of momentum transport for freely falling material will be equal to this pressure. The free-fall velocity is

$$v_f = \left( \frac{2GM}{R} \right)^{1/2} \quad (3)$$

The mass flux necessary to produce the total stellar luminosity is

$$\rho v = \frac{R}{GM} \frac{L}{4\pi R^2} \quad (4)$$

Hence

$$\rho_f v_f^2 = \frac{N_0}{\mu} k T_c \rho_c \quad (5)$$

from which we find

$$\rho_c = \frac{3L}{2^{5/2} \pi G^{3/2} M^{3/2} R^{1/2}} \quad (6)$$

The coronal scale height in this region is

$$H_c = \frac{N_0 k T_c R^2}{GM\mu} \quad (7)$$

Thus for one solar mass the amount of material overlying this point in the corona is

$$\rho_c H_c = 1.17 \times 10^{-3} R^{\frac{1}{2}}$$

For a neutron star  $\rho_c H_c = 1.17$  g cm<sup>-2</sup>. For the  $\gamma$ -rays which will be radiated in this case the effective cross-section is less than the Thomson cross-section. Thus the optical depth is not too large and the incoming material can radiate without much absorption. For a white dwarf,  $\rho_c H_c = 16.5$  g cm<sup>-2</sup>, however, which indicates that the foregoing crude picture is not quite correct; the infalling material will stop close to the photosphere. It is necessary to determine where the radiation will occur in this case.

Of course, the infalling material is not completely stopped, because the incoming mass flux must be constant. Let us consider the fractional energy radiation,  $\Delta E/E$ , of the material as it moves through a coronal scale height with the properties estimated here. The rate of energy radiation by thin-source bremsstrahlung<sup>6</sup> is  $\sim 2 \times 10^{-27} T^{\frac{1}{2}} n_e n_i$  ergs cm<sup>-3</sup> sec<sup>-1</sup>, where  $n_e$  and  $n_i$  are the number densities of electrons and ions. We write the energy loss rate as  $2 \times 10^{-27} T^{\frac{1}{2}} N_0^2 \rho / 4\mu^2$  ergs g<sup>-1</sup> sec<sup>-1</sup>. The time required to move through a scale height is  $H_c/v$ , and the energy available for radiation is  $E = GM/R$  g<sup>-1</sup>. Hence

$$\frac{\Delta E}{E} = 2 \times 10^{-27} \frac{T_c^{\frac{1}{2}} N_0^2 \rho_c}{4\mu^2} \frac{H_c}{v} \frac{R}{GM} \quad (8)$$

From equations (2), (4), (6) and (7) we have

$$\frac{\Delta E}{E} = \frac{3^{\frac{1}{2}} \times 10^{-27}}{2^{5/2} \pi} \frac{N_0^{3/2} L R^{3/2}}{k^{\frac{1}{2}} G^{5/2} M^{5/2} \mu^{3/2}} \quad (9)$$

For one solar mass this becomes

$$\frac{\Delta E}{E} = 5.5 \times 10^{-13} R^{3/2}$$

For a neutron star this is  $5.5 \times 10^{-4}$ , showing that negligible radiation occurs before the infalling material is slowed and attains its high temperature. For a white dwarf star  $\Delta E/E \approx 1.5$ . This appears to indicate that the gas energy will be radiated away as the material slows down, but it must be remembered that a full scale height of gas is optically thick, and the value of  $\Delta E/E$  by the time the material has penetrated to a depth of  $\sim 1$  g cm<sup>-2</sup> is  $\sim 1.5/16.5 \approx 0.09$ . Thus in this case also the material arrives in the vicinity of the photosphere with most of its energy intact.

If all the released energy were to be radiated as black-body radiation from the photosphere, the photospheric temperature would be

$$T_e = \left[ \frac{L}{4\pi\sigma R^2} \right]^{\frac{1}{4}} \quad (10)$$

With  $L = 1.6 \times 10^{37}$  ergs sec<sup>-1</sup>

$$T_e = \frac{1.22 \times 10^{10}}{R^{\frac{1}{2}}}$$

For a neutron star the photospheric temperature will be  $\sim 1.2 \times 10^7$  °K, and for a white dwarf it will be  $\sim 8.6 \times 10^5$  °K. These temperatures are very much lower than the coronal temperatures. Thus it is evident that a steep temperature gradient must be set up near the photosphere.

We must consider thermal conduction of energy in the presence of such a temperature gradient. The conducted energy flux is  $\lambda dT/dz$ , where  $\lambda$  is the coefficient of thermal conductivity and  $z$  is the vertical distance in the atmosphere. For an ionized gas we may take<sup>7</sup>

$$\lambda = 5 \times 10^{-7} T^{5/2} \text{ ergs cm}^{-1} \text{ sec}^{-1} \text{ °K}^{-1}$$

For the purpose of a crude estimate let us write for the ratio of the energy conducted out of the photospheric scale height, during the time of passage of material through the scale height, to the energy content of the scale height as

$$\frac{1}{EH_c \rho_c} \lambda \frac{T_c H_c}{H_c} \frac{H_c}{v} = 3\pi \times 10^{-6} \left( \frac{2}{3} \frac{GM\mu}{N_0 k} \right)^{7/2} \frac{1}{R^{5/2} L} \quad (11)$$

For one solar mass this is  $1.8 \times 10^{20}/R^{5/2}$ . For a neutron star the result is  $1.8 \times 10^5$ , indicating that conduction can most easily remove the thermal content of the gas during its motion toward the photosphere. This conclusion would not be altered if a proper relativistic treatment had been used. For a white dwarf star the ratio is 0.32. For this case, however, a better estimate would be  $0.32 \times 16.5 = 5.3$ , and again conduction can remove much of the thermal content of the gas during its motion toward the photosphere.

It is evident that with a neutron star a very small temperature gradient is sufficient to conduct away the energy flux from the coronal region. Thus the temperature gradient will not become steep until very near the photosphere. In both kinds of star the steep part of the temperature gradient thus occurs within a photospheric pressure scale height and both temperature and density will change rapidly at almost constant pressure.

It is further evident that the conductive transport of energy will no longer be able to exceed the mass transport when the temperature is lower, because the thermal conductivity varies as a fairly high power of the temperature. We may roughly estimate that the two transport rates are equal at the radiation temperature of the gas, and thus this radiation temperature will be the coronal temperature reduced by the expression in equation (11) raised to the power 2/7. Thus, in the foregoing example the neutron star would radiate thin-source bremsstrahlung at

a temperature near  $2 \times 10^{10}$  °K, and the white dwarf would radiate at a temperature near  $2 \times 10^9$  °K.

It is evident that we do not find support in these results for Shklovsky's suggestion that the Scorpius X-ray source results from mass accretion on to a neutron star. For neutron stars the radius is a rather insensitive function of the mass<sup>8</sup>, and thus any reasonable adjustment of the parameters in the expressions given previously will not significantly lower the temperature at which the infalling material will radiate. Mass accretion on to neutron stars should give combination X-ray and  $\gamma$ -ray sources. The X-radiation results from the absorption of the thin-source bremsstrahlung by the photosphere and its re-radiation in a blackbody spectrum. Half the stellar luminosity will arise from this process, so that equation (10) should be modified to become

$$T_e = \left[ \frac{L}{8\pi\sigma R^2} \right] \quad (12)$$

Thus the blackbody spectrum of a neutron star in our example should have a temperature of  $10^7$  °K.

It is also evident that we have a much better chance of fitting the parameters of the Scorpius source if we assume a model with mass accretion on to a white dwarf. The masses and radii of white dwarfs are inversely correlated, and thus a much wider variation in parameters is possible. Because in our previous example the radiation temperature has come out too high, we must choose a lower mass which will have a larger radius. It is immediately evident from equation (11) that the conductive transport of energy will then become much less efficient, and the star will radiate at more nearly its coronal temperature. From the tabulated models of white dwarf stars<sup>9</sup>, it can readily be found that a white dwarf with a mass near 0.2 solar masses will have a coronal temperature near  $10^8$  °K. Its radius will be about  $1.4 \times 10^9$  cm. For this case the upper limit on the luminosity from the radiation stress condition is  $3 \times 10^{37}$  erg sec<sup>-1</sup>, which is somewhat higher than the apparent Scorpius luminosity. The total rate of mass infall needed to produce this luminosity is about one solar mass per  $10^6$  years.

These numbers are suggestive of the results obtained for the evolution of a close binary pair of stars by Kippenhahn, Weigert, and Kohl<sup>10,11</sup>. In their model the stellar primary transfers mass to the secondary after reaching the red giant phase; the transfer time is less than  $10^6$  years. The remnant settles down as a white dwarf star of 0.26 solar masses; it has an envelope which is rich in hydrogen and thus a somewhat larger radius than a pure helium white dwarf. If such an object exists in the Scorpius X-ray source system, we would therefore lower the estimate of coronal temperature somewhat. Of course, we would see the system at a later stage than indicated by the final models of Kippenhahn and Weigert, when the secondary had also evolved to the red giant stage and is transferring mass back to the original primary.

For  $M = 0.2$  solar masses and  $T_e = 10^8$  °K, the ratio of coronal pressure to photospheric pressure would be increased over the previous estimate by a factor of  $\sim 30$ . From equation (9) we see that  $\Delta E/E$  would be increased by a factor  $\sim 10^3$ , so that the infalling material will radiate thin-source bremsstrahlung before the bulk kinetic energy has been fully converted to thermal energy. From these results it is evident that an effective photosphere will develop in the infalling material, and thus conductive effects will not be important. The estimate for the coronal temperature is too high also for this reason. A steep temperature gradient will be set up near the effective photosphere. As the velocity of the infalling material will rapidly decrease along this temperature gradient according to the continuity equation (4), the bulk of the thin-source bremsstrahlung will be produced in a narrow shell near the photosphere.

From equation (12) we see that the photospheric temperature required to re-radiate the absorbed X-ray energy

will be  $3.3 \times 10^8$  °K. The spectrum will therefore show a peak near the 44–60 Å band in which Byram, Chubb and Friedman<sup>12</sup> have observed an additional component of X-irradiation from the Scorpius source. Their estimate of the interstellar opacity at 44 Å is based on an assumed ratio of hydrogen : helium of 7, but we prefer to assume double this number, which would be more characteristic of solar abundances. At an assumed distance of 200 parsec, and with an interstellar gas density of one hydrogen atom per cubic centimetre, 44 Å radiation is attenuated by one order of magnitude. Thus, in the absence of attenuation, Byram *et al.* should have seen about  $10^{-6}$  erg cm<sup>-2</sup> sec<sup>-1</sup> in the 44–60 Å band, corresponding to a luminosity of  $\sim 4 \times 10^{36}$  erg sec<sup>-1</sup> in this band from the Scorpius source. This is an order of magnitude higher than the previous discussion of our model would indicate.

We do not believe, however, that this is necessarily a difficulty with our model. We have seen that there is a rapid transfer of mass through the photosphere. If the total luminosity of the Scorpius source corresponds to the radiation stress limit, with much of the gravitational energy release occurring inside the photosphere, then the photospheric luminosity could be higher than the X-ray luminosity by a substantial factor. The white dwarf mass could also be substantially higher than 0.2 solar masses.

It is unlikely that the rapid rate of mass transfer to the white dwarf star can continue for a very long period without producing significant effects in the white dwarf itself. When a thick surface layer rich in hydrogen has been added, the source of the hydrogen-burning shell will be activated, and there may be an instability which will lead to nova explosions which will prevent the total mass from increasing too rapidly.

Because the binary companion will fill its Lagrangian surface in order to carry out rapid mass transfer, it will subtend a solid angle at the white dwarf of about  $\pi$ . Thus about a quarter of the white dwarf luminosity will be absorbed and re-radiated by the companion. There will be a large variation in the radiating temperature, but its general range will be of the order  $T \sim (L/4\pi R_c^2 \sigma)^{1/4}$ , where  $R_c$  is the radius of the companion. If we take  $L \sim 8 \times 10^{37}$  erg sec<sup>-1</sup> and  $R_c \sim 2 \times 10^{11}$  cm, then  $T \sim 4 \times 10^4$  °K.

The thin-source bremsstrahlung radiation will have a low-energy tail which will make a substantial contribution to the optical emission, as observed. The re-radiation by the white dwarf is peaked at a sufficiently high energy that there will be no substantial contribution in the visible. On the other hand, the re-radiation by the companion is peaked at a sufficiently low temperature that a substantial visible contribution is likely. We would therefore expect a variable visible luminosity, with a regular component due to orbital motion and an irregular component due to variable gas streams between the stars. The emission lines could well vary with respect to the continuum in this model.

We thank Drs D. B. Melrose, S. E. Kayser, W. D. Arnett, S. A. Colgate and H. Friedman for valuable discussions. This research has been supported in part by grants from the National Aeronautics and Space Administration.

# Conifer Distributions and Continental Drift

by

P. H. A. SNEATH

MRC Microbial Systematics Research Unit,  
University of Leicester

The distribution of fifty-eight genera of conifers over the world has been analysed statistically in order to group corresponding areas of the world's surface together. The results tend to confirm the existence of a Gondwanaland.

At a recent symposium at the University of Leicester, there was renewed discussion on how fossil faunal and floral distributions can contribute to information on continental drift. This is a topic that has attracted attention lately and is part of the wider problem of reconstructing the geography of the past<sup>2-12</sup>. The underlying logic is that if two areas have very similar faunas or floras, they were probably close together geographically; but it has always been clear that many factors interfere with simple interpretations of this principle.

It is therefore interesting to see how far floristic and faunistic difference does in fact reflect geographical distance, using known distributions of the present day, and to have methods for constructing the best fitting maps from biological data. This is needed to allow the interpretation of geological data, and to give some guide to the amount of disturbance produced by oceans, deserts, climatic zones, migratory or relict populations and so on.

The first step is clearly to construct a measure of difference in faunistic or floristic composition which may be termed "biotal distance". Many such measures are used in ecology<sup>13</sup>. They should be based on taxa recorded from a well spread series of sites for one time horizon. There are great problems of sampling and taxonomic

reliability<sup>5,6,8</sup>, which will not be dealt with in detail here. Even for living organisms, data of the quality and quantity needed may be difficult to find.

The next step is to arrange the sites into a map that reflects biotal distance. Relationships between the sites will be multidimensional, so that some way of reducing the dimensionality is needed. Factor analysis is applicable here, and is more rigorous than earlier ordination methods<sup>13,14</sup>. Although it is not difficult to get a good idea of the relations between a few sites (or organisms) by simple inspection, a systematic method is needed to deal impartially with all the data. The agreement between geographic and biotal maps can be measured by a recently described method if desired<sup>15</sup>. For restricted areas that can be regarded as a plane, the reduced dimensions will be two, and from the factor loadings the distorted biotal map can be drawn. For a roughly linear transect even simpler methods may suffice, and Fig. 1 shows an example based on Valentine's data on marine molluscs of the west coast of North America<sup>16</sup>.

For distributions covering the whole world, the required result will be a fitting to a sphere. This is in effect to allow the sampled sites to slide about the globe until their configuration fits best the biotal distances (expressed

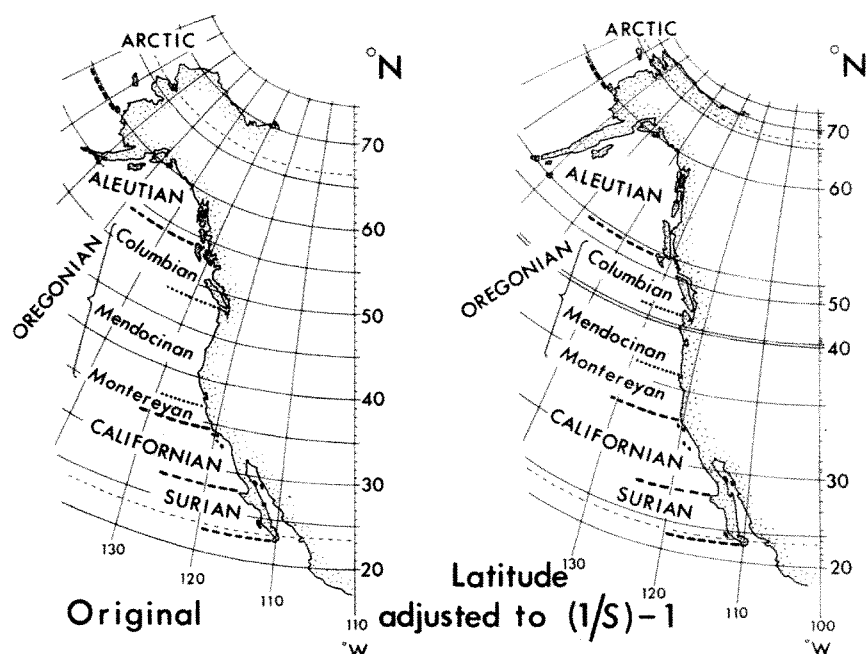

Fig. 1. The Pacific Coast of North America showing the marine faunal provinces and subprovinces of Valentine (1966). The map on the right has been obtained by using as a measure of biotal distance  $D = (1/S) - 1$ , which was found empirically to fit Valentine's  $S$  coefficients, and by displacing the shore line in latitude (though not in longitude).

as arcs). By extracting three factors, the positions of the sites are obtained in three dimensional space. Projection from the centroid on to a surrounding sphere will then give a fitting of the kind required. A point very close to the centroid will perhaps have an indeterminate position (small changes in biological composition due to sampling errors, for example, will alter the projection considerably) but this is unavoidable. Such a point represents a country that is almost equidistant biotically from all other countries, and it cannot be given a unique position on a globe. The closeness to the centroid will, however, indicate which points are most liable to this uncertainty.

This method has been applied to the present day distribution of conifers (including taxads). They were chosen because they are well documented, well classified, relatively non-mobile, and have a long evolutionary history. The fifty-eight living genera have been mapped by Florin<sup>17</sup> for the whole world. Only present day distributions (excluding human introductions) were used from those data, because the fossil records are not available for a world-wide series of sites at a single time period. Minor extensions of range<sup>18</sup> were not considered, and sections of genera, being of uncertain taxonomic validity, were not distinguished. The land masses of the globe—or all that possess conifers—were divided into fifty-eight “quadrats” of approximately equal area (some difficulty was found with archipelagoes, etc.), as shown in Fig. 2. Florin’s maps were overlaid by these quadrats on a transparent sheet, and the presence of the genera (in any part of a quadrat) was scored. The resulting table was treated as 1,0 data and the four point correlation coefficient  $\phi$  was computed between all pairs of quadrats, and used for principal component analysis. The first three vectors accounted for 29.27, 23.67 and 7.65 per cent of the variation respectively. No points were very close to the centroid; the closest were the points representing quadrats 26, 27 and 29 (between 0.24 and 0.29 from the centroid) and the most distant were 45 and 47 (both 0.80 from the centroid).

The loadings on the three vectors ( $x$ ,  $y$  and  $z$ ) give the best three-dimensional representation of the data. The points were fitted to a globe by projection from the centroid of the three vectors; first the vector means were subtracted from the loadings (the means were 0.4497, -0.2230 and 0.0348 respectively) and then the following formulae were used:  $\sin(\text{latitude}) = y/\sqrt{x^2 + y^2 + z^2}$  and  $\tan(\text{longitude}) = z/x$ . Although this projection will show

the points in their correct relative positions, it will not show what axis corresponds to geographical north and south. To find this, the projection was rotated by a three-dimensional method<sup>15</sup> to give the best fit between the points and the centres of the present-day quadrats in Fig. 2.

The resulting fitted projection is shown in Fig. 3. The confidence limits to be placed on these positions are not readily estimated, but a rough estimate was made as follows. The standard error of sampling of a correlation coefficient based on  $n$  items is about  $1/\sqrt{n-3}$ , in this case 0.135, and, treating  $\phi$  as a cosine, this represents about 7.7°. The shift of origin may increase this by a few degrees, but it is probably little changed by the principal component analysis. Cones on the globe of radius 10 and 20 degrees of arc will be about 1 and 2 standard errors respectively. The larger cone will therefore indicate roughly the 95 per cent confidence limits for the position of a point. The standard error may be somewhat unrealistic (because all living conifers were used) but it is an indication of the error one might expect if one had taken fifty-eight genera from a larger sample with the same distributional pattern as the conifers. To this extent it is a guide to reliability in such studies.

It is not clear whether, for studies of this kind, one should make the variances for the three vectors equal. This would have the effect of making the cluster of points roughly spherical instead of ellipsoidal before projection onto the globe, and can be achieved by dividing the loadings by the square roots of the latent roots. In the present case this would make little difference to the main features of Fig. 3, as the square roots for the vectors were respectively 4.12, 3.71 and 2.11. This would only lead to a somewhat more even spreading of points with respect to longitude.

It is seen by comparing Figs. 2 and 3 that the biotal distances differ a good deal from the present geographical distances. Nevertheless the index of misfit<sup>15</sup> between the figures,  $d_h^2$ , is 0.792 with standard error 0.148. The expected value of  $d_h^2$  for random points is 2.0, so there is better agreement between present day geography and the biotal distances than one would expect by chance, and this is highly significant statistically. It may perhaps be permissible to regard  $d_h^2$  as a measure of the variance that is “unexplained” by geography, out of the 2.0 expected, so that in this case 60.4 per cent of the variation in the first three vectors is “explained” by the present day

Fig. 2. The fifty-eight land areas possessing conifers that were used for analysis (Mollweide's projection).

geography. The percentage of total variation thus explained is rather lower, because these vectors themselves account for only about 60 per cent of the total variation.

Conifer distributions have often been cited as evidence for the theory of continental drift, and in particular for the southern continent of Gondwanaland. The points in Fig. 3 do bear some resemblance to the postulated positions of the continents in the later Palaeozoic on this theory, especially for the southern continents<sup>7,9,12</sup>. Numerical evidence for this is not easy to obtain: no reconstructions of the position of all the continents for the Carboniferous or Permian seem available; partial reconstructions raise serious statistical problems. The most complete reconstruction available at present is that of Irving (in ref. 1) for the Permian (based mainly on palaeomagnetic evidence), and  $d_h^2$  between that and Fig. 3 was found to be 0.692, with standard error 0.157. Though the fit is better than with present day geography this is not statistically significant. Clearly, more detailed geological evidence is needed to explore this further, but a few very tentative comments on the resemblances between Fig. 3 and the Palaeozoic land-masses may be added. The southern points approximate to the concept of Gondwanaland before it broke up in the Permian and Triassic<sup>9</sup>. Points for South America, southern Africa and southern India are grouped fairly closely, and those for Australia are relatively isolated; this is in keeping with reconstructions of Gondwanaland<sup>7,9,12</sup>. The difference in floras on the east and west of the Kalahari desert (indicated by the separation of points 32, 42 and points 33, 34, 43, 44) may have no significance. The holarctic points are closely grouped (as the uniformity of the conifers in this region would lead one to expect), and there is nothing to suggest the pattern of the northern Palaeozoic floras discussed by Just<sup>4</sup>.

It should be made plain that the points in Fig. 3 represent roughly the centres of the quadrats in Fig. 2, and that finer spacing of quadrats would presumably show many of the existing land links as a distorted geographical map. It was not feasible to draw such a map in this instance because of the complexity of the relationships between the points. Also, a number of quadrats are placed together because they possessed just one genus of

conifer. Thus quadrats 20 and 21 both possess only *Juniperus*, and southern India (No. 35) is placed with western Africa and central South America (Nos. 32, 39, 40, 42) because they all have only the genus *Podocarpus*. The weight to be placed on such slender evidence depends on how significant it is that they do not have any of the other genera. There seems to be relatively little influence of deserts and ice-caps compared with oceans, as is generally recognized<sup>10</sup> (except for the Sahara, which may be involved in continental drift).

Conifers would seem to be reasonably good for the kind of study made here. Though mostly monoecious, they probably do not migrate very readily. The genera listed by Florin are reasonably uniform phenetically, though the position of some southern quadrats might be rather different if *Podocarpus* (which is more diverse than most) had been divided into several genera. Ideally one should first make a numerical taxonomic study to obtain taxa of equal phenetic rank; this would be important with data such as labyrinthodont fossils<sup>10</sup>. Although fossil conifers were not considered (and many genera had a much wider distribution in the past<sup>17</sup>) this does provide a realistic example for studies where fossil evidence is not available. The positions of southern points in Fig. 3 can be interpreted in terms other than continental drift. Thus Darlington<sup>11</sup> considers it more probable that the present distributions are the result of spread by way of the tropics (though the present day southern genera do not seem to have moved into the northern hemisphere) and he believes that such distributions may reflect ancient climates rather than past land connexions.

One might suppose that for non-mobile organisms the reconstructions would reflect the position of land masses at the time when the main radiative evolution took place. The conifers appear to have arisen in the late- or mid-Carboniferous, and radiated soon after<sup>17</sup>, but there may have been several radiations, which would obscure the interpretations<sup>10</sup>. Presumably there would be little trace of periods before the evolutionary origin of the group.

It is clear from Fig. 1 that there are also biological distributions that reflect rather well the present geographical relationships. In that example, as Valentine pointed out, the biggest influence is clearly that of tem-

Fig. 3. The positions of the points representing the fifty-eight quadrats as given by the analysis of conifer distributions. The quadrat numbering is the same as in Fig. 2. The conventional biogeographical provinces are indicated. ●, Holarctic; ○, Oriental; ■, Ethiopian; □, Neotropical; △, Australian.

perature, largely due to ocean currents. There are also no important barriers to migration (other than climate) and the area is believed to have been a single geographical entity for a considerable time.

On more general points it should be noted that we need to know the probabilities of dispersal and migration (little information is usually available on this) if we are to assess the evidence for land connexions<sup>3,6</sup>. One must also guard against selecting simply those distributions that support some hypothesis<sup>10</sup>. These requirements may be conflicting, and one may have to make judgments on slender grounds. The most satisfactory approach seems to be to choose a large taxon of non-mobile organisms and to consider all the subtaxa within it, and then to use a statistical method such as factor analysis. In particular, one should note that the reconstructions may relate, not to the time for which the distributions are mapped, but to an unspecified time earlier to this.

I thank Professor E. Irving, Dr R. Melville, Miss A. P. Conolly and Dr M. A. Khan for helpful criticism, and M. J. Sackin for assistance with computing.

## Fallout Caesium-137 and Potassium in New-born Infants

by  
A. R. WILSON\*  
F. W. SPIERS

Environmental Radiation Research Unit,  
Department of Medical Physics,  
University of Leeds,  
General Infirmary, Leeds 1

New techniques of low background counting have made possible the measurement of intake and retention of natural potassium and caesium-137 in infants. The biological half-lives of both potassium and caesium-137 are from 5 to 10 times lower than the corresponding values in adults.

Low background counting techniques have recently been developed to such an extent that both the natural potassium and the caesium-137 contents of infants can be measured with an overall accuracy (see below) of about  $\pm 7$  and  $\pm 10$  per cent respectively<sup>1</sup>. The uptake and retention of the isotope caesium-137 in the body is somewhat similar to that of potassium and it is known, from a number of investigations, that the biological half-life for caesium-137 in the adult averages about 100 days for the principal component, comprising about 90 per cent of the intake by ingestion<sup>2</sup>. The other, smaller, component is excreted with a short biological half-life of a little over one day<sup>3,4</sup>. Little corresponding information is available for children; values of the biological half-life of caesium-137 in children have been reported as about 35 days in the age range 6–12 yr<sup>4,5</sup> and three values of about 21–25 days have been given for infants<sup>6</sup>. Two values of 7 and 10 days have also been reported for infants by Rundo (personal communication). There are general grounds for expecting the turnover of caesium-137 to be more rapid during the early years of growth than in adult life. The presence of fall-out caesium-137 in all milk products in recent years has made it possible to investigate the uptake of caesium-137 in the new-born infant, if both the intake of caesium-137 in food and the retention of the isotope in the body are measured. We have been able to make the necessary measurements of intake and retention, over the period from birth to 6 months in the case of four infants who were bottle-fed. The

feeding regime, which is described below, could only be carried out with very careful co-operation on the part of the mothers and the period of investigation was, perforce, limited to about 6 months, because a mixed diet was usually introduced at that time and it became technically difficult to make the measurements on the more active and restless child of that age.

The following scheme has been used to determine the caesium-137 and potassium intakes and the retained whole body burden of infants during the first six months of life: the infant was measured once every week for the first 2 or 3 months and once every fortnight from then onwards; after each measurement the mother was given a known amount of dried milk (sufficient to last until the next measurement); at each feed, all the wasted dried milk (for example, rinses from mixing bowls and bottles, together with any vomit or dried milk spilled) was collected in a large container; the mother returned for the next measurement with the remaining dried milk and the container of residues. The milk was weighed and the residues reduced in volume and measured for caesium-137 and potassium content. Knowing the caesium-137 and potassium content of the milk, the intake of the infant since the last measurement could then be calculated.

### Whole Body Counting of Infants and Mothers

Whole body burdens were measured using a whole body counter with sodium iodide crystals doped with thallium. It was housed in a steel cubicle which had walls 5 in. thick, in the sub-basement of a five storey

\* Present address: Department of Physics, Birkbeck College, Malet Street, London, W.C.1.

Fig. 1. Whole body counting geometry for infants.

building. The subject lay on a couch with two 6 in. diameter  $\times$  4 in. thick crystals fixed above the couch and another two fixed below.

Measurements of very young infants involved several difficulties not experienced in the measurement of adults and the following techniques were employed: in order to avoid changes in geometry during counting, measurement was only attempted with the infant asleep—usually and conveniently after the infant had been fed; the position and shape of the infant could not be defined exactly and it was necessary to use a crystal geometry which was as insensitive as possible to variations in these factors. This was achieved by placing the infant on the couch with the crystals arranged as in Fig. 1.

Calibrations were made with small polythene containers, filled with potassium and caesium-137 solutions, which approximated the mass and shape of the infant. The effect of a small distilled water (that is, inactive) phantom on the background count rate was negligible. In Table 1 the background count rate, caesium-137 and potassium sensitivities (c.p.m./nc. caesium-137 and c.p.m./g potassium) are recorded for a phantom, 6 kg in weight and 40 cm long, and for a phantom 10 kg in weight and 60 cm long. The sensitivity is not strongly dependent on the size of the infant nor on the exact position and shape of the infant—as was shown by measuring the sensitivity of phantoms simulating the possible positions and orientations of an infant on the couch.

The gamma ray spectrum of a new-born infant, after background subtraction, is shown in Fig. 2; the energy ranges chosen to cover the caesium-137 photopeak (B in Fig. 2), part of the potassium-40 Compton continuum (C) and the potassium-40 photopeak (D) are also shown. The whole body potassium was calculated from both of the

higher energy ranges corresponding to the photopeak and Compton continuum of the potassium-40 gamma ray spectrum; in all cases, good agreement between the two values was obtained. This indicated no additional gamma ray contaminant but also good matching of the spectra from infant and phantom. The whole body potassium contents reported in this paper were finally calculated from the summed count rates in the two high energy ranges. The whole body caesium-137 contents were calculated from the count-rate in the second energy range covering the caesium-137 photopeak corrected for the potassium-40 contribution. The count-rate in the lowest energy range (A), corrected for potassium-40 and caesium-137 contributions, showed that no significant amounts of low energy gamma emission and/or bremsstrahlung were present, and that any differences in scatter and absorption between infant and phantom were very small.

When possible, the infant and background were measured for at least 30 min and with a background counting time of 60 min the standard error in the counting statistics for the measurement of 1 nc. of caesium-137 and 8 g of potassium in an infant were approximately  $\pm 5$  per cent and  $\pm 8$  per cent respectively. Allowing for the further uncertainty, associated with differences between phantom and infant, the overall uncertainties are estimated to be  $\pm 7$  per cent and  $\pm 10$  per cent respectively.

The caesium-137 and potassium contents of the mothers were measured with the same whole body counter as the infants but with a different crystal geometry. The crystals were the same distance above and below the couch; one of the crystals was positioned over the mid-point of the subject while the other was displaced 40 cm towards the head. One of the lower crystals was displaced 70 cm from the mid-point towards the head, while the other was displaced 50 cm towards the feet. Calibrations were made with caesium-137 and potassium phantoms. The potassium contents were calculated from the same energy range (C + D) as that used for the infants.

### Measurement of Potassium and Caesium-137 in Dried Milk and Milk Residues

Samples containing 100 g of dried milk, made up with water to a standard volume of approximately 1 litre and contained in a 'Perspex' cylinder, were counted between two of the sodium iodide crystals. The residues were reduced to the same volume and measured in the same way.

Sufficient (homogenized) quantities of several brands of dried milk were measured and stored; from these a

Fig. 2. Gamma ray spectrum of new-born infant: the infant was 2 days old, weighed 3.9 kg, and was counted for 30 min; the standard errors shown are calculated for a background counting time of 100 min. Whole body contents calculated from this measurement were  $0.62 \pm 0.06$  nc. caesium-137 and  $7.7 \pm 0.7$  g potassium.

Brands A, B, C and D derived from English milk, brand E from Finnish milk.

measured potassium and caesium-137 contents. In the metabolic investigations on the four bottle fed infants, three infants were fed on milk A and one on milk C. It is probable that the different brands are derived from different parts of the country and it is perhaps surprising that the caesium-137 contents are so similar.

### Intake and Retention of Caesium-137 and Potassium

Values of the intakes and whole body contents of caesium-137 for one infant (infant C) are given in Table 3 and shown graphically in Fig. 3. The caesium-137 body content of the mother, measured several days after birth, is also listed in Table 3. Very similar data were obtained for the three other infants and mothers.

Mother	64.1	15.6			

\* Calculated assuming maternal and infantile concentrations of caesium-137 are equal at birth.

If, in the absence of evidence concerning the metabolic compartments for caesium-137 in infants, it is assumed

Fig. 3. Measured and calculated caesium-137 contents of an infant from birth to age 6 months. ●, Measured content with standard error; ○, calculated content.  $T = 12$  days.

that the metabolism can be represented by one compartment with a biological half-life of  $T$  days, values of the expected whole body retention can be calculated from the intake data by suitable choice of  $T$ . If  $P$  is the average intake per day over an interval  $t$  days, the compartment content  $Q$  at the end of the interval is given by

$$Q = Q'e^{kt} + \frac{P}{k}(1 - e^{kt})$$

where  $k = 0.693/T$  and  $Q'$  is the compartment content at the beginning of the interval. The value of  $Q'$  at birth can be deduced approximately from the concentration of caesium-137/kg in the mother because, as will be shown later, the calcium-137 concentrations in mothers and infants are almost the same. Calculated values of the caesium-137 content of an infant can then be derived step-wise from the successive values of the intake on the basis of this equation. The contents of the infant C, calculated in this way, are listed in the last column in Table 3, and are compared with the measured whole body retentions in Fig. 3. It can be seen that good agreement with the measured values is obtained by using a value of  $T$  of 12 days. Similar treatment of the data for two other infants gave values of 11 and 14 days for the biological half-life, extending over periods of about 140 days. In the case of the fourth infant, the measured caesium-137 content could be represented by a value of  $T$  of 11 days up to age 81 days and followed by a value of 13 days to age 154 days.

The assumption of a more elaborate model of caesium-137 metabolism in the infant was hardly justified by the results available by this method of investigation, for the existence of a small short-lived component in infants, as in adults<sup>3,4</sup>, would only increase the values of  $T$  derived here by about 10 per cent. To establish the presence of such a component would necessitate giving a small (but unjustifiable) amount of caesium-137 as a single dose.

The intake of potassium and the body content of potassium are given for infant C in Table 4 and also shown graphically in Fig. 4. Although the concept of a biological half-life is difficult to apply in the context of an essential physical ion like potassium, we have nevertheless derived values of the biological half-life  $T$  by treating the potas-

Table 4. MEASURED AND CALCULATED POTASSIUM CONTENT OF AN INFANT FROM BIRTH TO 6 MONTHS

Mother	64.1	108.4	1.69			

\* Calculated assuming maternal and infantile concentrations of potassium are equal at birth.

sium data in the manner described for caesium-137. It can be seen that a good fit, between the measured potassium contents and those calculated for the one compartment model, is obtained with a value of  $T$  of 6 days up to age 100 days, beyond which a better fit is obtained with a value of  $T$  of 6.5 days. A similar increase in the value of  $T$  was found to be necessary for two of the

other three infants; for one,  $T$  increased from 5 to 7 days at 81 days, and for the other infant,  $T$  increased from 5 to 6 days at age 93 days. For the fourth infant, a good fit over the whole duration of the measurements (150 days) was obtained with a value of  $T$  of 4.5 days.

The values of the biological half-life  $T$  for both caesium-137 and potassium for the four infants investigated are assembled in Table 5. All the values of  $T$  for caesium-137 are less than those reported for older children<sup>4,5</sup> and very much less than those for adults<sup>2</sup>. The average value of about 12 days for  $T$  (caesium-137) is also less than values of 21–25 days reported by Bengtsson *et al.*<sup>6</sup> for three infants born to mothers who had considerable caesium-137 and caesium-132 burdens but in these cases the derived values of  $T$  depend on corrections which have to be made to allow for the intake of breast milk.

Table 5. COMPARISON OF CAESIUM-137 AND POTASSIUM DATA

Infant	Caesium		Potassium		Ratio $T(^{137}\text{Cs})$ $T(\text{K})$
	Period (days)	$T$ (days)	Period (days)	$T$ (days)	
A	0–81	11	0–81	5	2.2
	81–154	13	81–154	7	1.9
B	0–149	14	0–72	5	2.8
			72–149	6	2.3
C	0–183	12	0–108	6	2.0
			108–183	6.5	1.9
D	0–145	11	0–145	4.5	2.5

The values of  $T$  (potassium) in Table 5, like those for caesium-137, are also very much less than the biological half-life taken for potassium in adults<sup>7</sup>. The ratios of  $T$  (caesium-137) to  $T$  (potassium) given in the last column average about 2.2, and this is consistent with a discrimination factor of 2 for the caesium-137 to potassium ratio in adults with respect to that in diet, reported by Langham and Anderson<sup>8</sup>.

The caesium-137 and potassium contents of nine mothers and their infants were measured within 3 days of parturition. The results are listed in Table 6, together with values for the concentrations of caesium-137 and potassium, in nc. and g respectively per kg of body weight. The concentrations in the infants are plotted against those in the mothers in Fig. 5 for potassium and in Fig. 6 for caesium-137.

If there is no placental discrimination it is to be expected that the infant contents of caesium-137 and potassium will reflect the plasma concentrations of these elements during foetal life. If the relative proportions of different tissues and organs were the same in mother and infant, the concentrations of caesium-137 and potassium/kg in

Fig. 4. Measured and calculated potassium contents of an infant from birth to age 6 months. ●, Measured content with standard error; ○, calculated content.  $T = 6$  days; ○, calculated content.  $T = 6.5$  days.

Fig. 5. Potassium concentrations in mothers and new-born infants.

the infant should be close to those in the mother. The results for potassium in Fig. 5 show that the infant potassium concentration is usually about 10 per cent above that of the mother, reflecting some difference in body composition, such as possibly less fatty tissue (which contains little potassium) in the infant than in the adult.

Table 6. POTASSIUM AND CAESIUM-137 CONTENTS OF MOTHERS AND THEIR NEW-BORN INFANTS

Subject + infants' age	Weight (kg)	$^{137}\text{Cs}$ content (nc.)	Potassium content (g)	$^{137}\text{Cs}$ concentration (nc./kg)	Potassium concentration (g/kg)
Mother 1	65.2	10.0	105.7	0.154	1.62
Infant 1, F (1 day)	3.35	0.51	6.2	0.152	1.84

Infant 4, M (2 days)	3.60	0.44	6.7	0.119	1.80
Mother 5	56.7	10.4	96.3	0.183	1.70
Infant 5, M (2 days)	3.86	0.62	7.7	0.161	2.00
Mother 6	69.6	9.3	94.1	0.134	1.85
Infant 6, F (2 days)	3.01	0.47	6.8	0.156	2.26
Mother 7	57.6	8.7	92.3	0.151	1.60
Infant 7, M (3 days)	3.06	0.60	5.7	0.196	1.86
Mother 8	49.5	5.2	86.9	0.106	1.76
Infant 8, F (2 days)	3.91	0.45	7.3	0.115	1.87
Mother 9	68.7	6.8	94.1	0.099	1.37
Infant 9, F (2 days)	5.0	0.31	7.8	0.062	1.57

The caesium-137 concentrations in Table 6 and Fig. 6 are very similar in mother and infant. Departure from this approximate equality might well occur, however, in view of the differences in the biological half-life of caesium-137 of adults and infants and the variability of the dietary intake of the isotope. The value of  $T$  of 70–100 days in the adult means that the caesium-137 content of the mother depends on the dietary intake over a period of the order of 6 months or more. The caesium-137 content of the infant, with a value of  $T$  of only 12 days, reflects the plasma concentration in the mother over the last month of pregnancy and thus on the dietary level during this shorter and later period. The quite considerable differences between mother and child in some of the caesium-137 concentrations in Table 6 are compatible with this hypothesis.

The measured concentrations of caesium-137/kg can be used to derive the consequent internal radiation dose to the body tissues. For the caesium-137 levels at the

Fig. 6. Caesium-137 concentrations in mothers and new-born infants.

time of the measurements (1964) the dose rate to the infant was about 1 mrad/yr at birth and about 2 mrad/yr at 6 months. These values correspond approximately to 1 and 2 per cent respectively of the dose rate from natural background radiation.

We thank the Medical Research Council for support. We also thank Professor J. S. Scott and Dr E. C. Allibone for their help in obtaining the collaboration of the mothers of the infants measured. We are particularly indebted to the four mothers who took part in the metabolic investigation and followed the feeding regime so carefully. We also thank Mr Brian Oldroyd for assistance in making the measurements and Dr F. B. Ellis for help in obtaining some of the samples of dried milk.

## Weather and Discharge Data used to compute Dose Rates from Coastal Discharges of Radioactivity

by

F. MORGAN

Ministry of Agriculture, Fisheries and Food,  
Marina, Lowestoft

Some of the waste material discharged into the sea from the Dounreay reactor establishment settles on the nets used by fishermen in the area. The dose rate to their hands is a function of the discharge rate and the local conditions around the fishermen's nets. Equations derived on this basis show a close agreement with findings in the field.

LIMITED amounts of dilute aqueous radioactivity from the Dounreay Experimental Reactor Establishment are discharged by pipeline into the coastal waters of Caithness<sup>1</sup>. Almost 2 miles away from the outlet fishermen work large fixed-net installations between May and the end of August each year. During those months the water along that coast is remarkably clear, but its continual movement through the nets leads to the deposition on the meshes of fine particles of inorganic and organic matter, mostly below 5 $\mu$  in diameter, but including some clusters, mostly below 50 $\mu$  in diameter; these particles may carry varying amounts of adsorbed radioactivity as a result of the discharges to sea. One of the restrictions on the rate of discharge is based on the beta radiation exposure to the hands of fishermen working the nets.

The physical features of the coastal area, and the relation of Dounreay to Sandside Bay in which the nets are worked, are shown in Fig. 1. There are prominent reefs along the coast, backed up by low rocky cliffs as far as the bay, and high cliffs beyond.

During the course of making regular measurements—up to twice a week during the summer season—of the beta radiation dose rate received on contact with such nets, an overall pattern of higher dose rates during calm weather and lower dose rates during rough weather emerged. For purposes of measurement a stretch of net—2 fathoms deep, suspended from floats and weighted with rope along the bottom edge—was set within a short

distance of the commercial nets. After lifting the net, measurements of dose rate were taken using GM tube and ionization chamber instruments. A short account of part of the work carried out since 1962 is given here.

Fig. 1. Coastal features between the Dounreay Experimental Reactor Establishment and Sandside Bay, showing depths, reefs, contours and position of net.

It was supposed that the dose rates from the nets would be determined by (1) the rate of discharge from DERE and (2) local conditions round the nets. It was further supposed that wind strength determined the conditions around the nets, both as regards (2.1) the state of the sea—which decided the amount of sediment in equilibrium on the meshes of the nets—and (2.2) the quantity of sediment in suspension in the top 2 fathoms of water. These two wind effects might be expected to act in opposition on the dose rate, for example, increasing wind strength reducing the stability of sediment on the nets, but increasing the amount of sediment available in the upper layers of water.

For the first analyses a simple power relation was assumed

$$r = c (d_d)^{b_d} (u_{ns})^{b_w} \quad (1)$$

in which  $r$  is the dose rate on the net;  $c$ , a constant;  $d_d$ , the mean daily discharge of activity, taken over a period of  $t_d$  days before dose measurement, either with or without correction for decay;  $u_{ns}$ , the mean wind speed, taken over  $t_{ns}$  days before dose measurement; and  $b_d$ ,  $b_w$ , are exponents relating to discharge and wind.

Values of  $b_d$  and  $b_w$  were found by partial regression analysis of log transformed discharge and wind data. Chemical Services, DERE, provided discharge data, based on total beta and individual gamma determinations; wind data were provided by Health Physics, DERE.

**Analysis of results of first season.** For each observation of dose rate the following data were prepared. (1) Mean daily discharge rates over periods of 15, 30, . . . 75 days before dose measurement, using (1.1) total beta data, and (1.2) gamma measurements relating to the 0.13, 0.5 and 0.75 MeV peaks, that is to  $^{141}\text{Ce}/^{144}\text{Ce}$ ,  $^{103}\text{Ru}/^{106}\text{Ru}$  and  $^{95}\text{Zr}/^{95}\text{Nb}$  pair totals. (2) Mean scalar wind speeds, that is, taken over bearings  $0^\circ$ – $360^\circ$ , over periods of 1, 2, . . . 21 days before dose measurement.

Referring to equation (1), all combinations of  $t_d$  (relating to discharge, between 15 and 75 days), and  $t_{ns}$  (relating to wind, between 1 and 21 days) were analysed to show the variations of  $b_d$  and  $b_w$  with times of averaging. For discharge periods of 45 and 60 days the values of  $b_d$  bracketed the value  $b_d = 1.0$ , that is, a linear relation between discharge rate and dose rate obtained for discharges averaged over periods of 45–60 days. Taking this linear relationship as a reasonable foundation, the (45 and 60 day discharge) (1–21 day wind) combinations were examined for variation of  $b_w$ , the wind exponent over the 1–21 day wind period;  $b_w$  showed plateau characteristics over the interval of 3–9 days' wind, taking values in the range  $(-1.6 \pm 0.3)$ . This preliminary analysis showed features that appeared in all subsequent analyses: (1) an indicated discharge summation period approaching 2 months; (2) plateaux relating to  $b_w$ , and  $b_d$ , when winds were averaged over periods of 5–9 days before dose measurement. The two periods of time under (1) and (2) gave the first indications of the time characteristics of the DERE/Sandside Bay system.

Figs. 2 and 3 illustrate results obtained using a (1 discharge/1 scalar wind) combination. The simplest estimate of dose rate was based on 60 days' discharge, total beta corrected for decay,  $b_d = 1.066$ , with 7 days' scalar wind,  $b_w = -1.776$ ; see Fig. 2. An improved fit was obtained using weighted gamma data: the weighting factors 1.0, 0.5 and 0 were fitted to the discharges assayed under the  $^{141}\text{Ce}/^{144}\text{Ce}$ ,  $^{103}\text{Ru}/^{106}\text{Ru}$  and  $^{95}\text{Zr}/^{95}\text{Nb}$  peaks respectively; Fig. 3 shows dose rates estimated from 60 days (Ce + 0.5 Ru) and 11 days' wind. For this combination,  $b_d = 0.986$  and  $b_w = 2.052$ , the  $b_w$  value falling just below the plateau range. The fit was satisfactory over the weighting ranges (0.3–0.7) for ruthenium and (0–0.1) for zirconium–niobium.

In further analyses subdivided periods of discharge and scalar wind were used: also vector winds, air temperatures and air/sea temperature ratios. All these addi-

tional steps were developed in the analysis of the results of three consecutive seasons, except the use of vector wind, which was dispensed with over the wind averaging period used, namely 10 days.

**Analysis of results of three seasons.** At Sandside Bay winds were low in 1962, mixed in 1963 and higher in 1964: dose rates measured through 1964 were lower than those of the previous years. It was supposed that this was due to the effect of sustained winds on the turnover of activity and sediment. To deal with this variation between seasons—in addition to that within a single season—a further wind term was used. Wind speeds were averaged over periods of 28, 42, 56 and 70 days and used in conjunction with discharge, and short period winds: best fits were obtained with the 42 day period—approaching the time range already indicated for the treatment of discharge data. These long period mean winds were used in two ways: (1) directly, as with the short period winds, to examine whether the between seasons effect was directly related to wind power; and (2) exponentially, in the form  $\exp(b_w u^n)$  in which  $n$  was varied between 3 and 5, on the supposition that reduction of dose rate could be due to loss of activity to sea-bed solids raised by wave breaking.

In the analysis of the results of the first season the estimates of dose rate were related to the individual days of dose measurement, whereas it is usual to operate the restriction on discharges from DERE on a monthly basis. To bridge this time gap it was decided to average dose rate measurements over two weekly periods when processing the results obtained over three seasons. Times given below for discharge relate to mid-fortnight as zero, and for the other parameters to 3 days later—a displacement indicated by fitting.

Fig. 4 shows a typical fit based on (1) 56 days' discharge gamma (Ce + 0.7 Ru + 0.1 Zr):  $b_d = 0.955$ ; (2) 10 days'

Fig. 2. Observed dose rates against dose rates computed from 60 days discharge (total beta) and 7 days scalar wind. —, Observed; ----, estimated.

Fig. 3. Observed dose rates against dose rates computed from 60 days (Ce + 0.5 Ru) discharge and 11 days scalar wind. —, Observed; ----, estimated.

Fig. 4. Two weekly average dose rates observed 1962-3-4, against dose rates computed from 56 days ( $Ce + 0.7 Ru + 0.1 Zr/Nb$ ), 10 days scalar wind, 7 days air/10 days sea temperature ratio, 42 days wind (direct method). —, Observed; ----, estimated.

Fig. 5. Comparison with Fig. 4, using 42 days wind (exponential method). —, Observed; ----, estimated.

short wind:  $b_{sw} = -1.547$ ; (3) (7 days air/10 days sea) temperature ratio:  $b_{a/s} = 0.936$ ; (4) 42 days' long wind:  $b_{lw} = -3.188$ .

The air/sea temperature ratio was best based on maximum air temperatures, and was taken over a time range (3-15 days) similar to that used for short winds. The value of  $b_{lw} = -3.188$  is a typical value from a range of  $-2.9 \pm 0.3$  indicated by many analyses. The fit shown in Fig. 4 was improved by subdividing the 56 day period into four periods of 14 days.

The alternative, exponentially based method, is illustrated in Fig. 5 using (1) 56 days' discharge gamma ( $Ce + 0.7 Ru + 0.1 Zr$ ):  $b_d = 0.956$ ; (2) 10 days' short wind:  $b_{sw} = -1.462$ ; (3) (7 days air/10 days sea) temperature ratio:  $b_{a/s} = 1.265$ ; (4) 42 days' long wind: using  $\exp(u_{42})^5$ :  $b_{ew} = -2.520$ .

Closer fits than those shown in Figs. 4 and 5 were obtained by taking decay into account, that is, by applying sliding weighting factors to the four separate 14 day periods of discharge.

Since these analyses were completed, tests of the two methods of using long wind have been made on measurements taken in the summer of 1965, and during the winter 1966-67. It appears that: (1) the use of direct long wind, that is, in the form  $b_{lw} = -3$ , is indicated; (2) the accuracy of dose rate estimation meets the discharge control requirement.

The overall range of averaging times used in these analyses—from the shortest wind to the longest discharge—runs from 1 day to 75 days. But when plateau characteristics are taken into account, two well-marked periods emerge: (1) about 5-8 weeks, relating both to discharges and the long-term winds; (2) 1-2 weeks relating to the local conditions around the nets, as determined by wind and temperature.

The exponent relating to the long-term wind ( $b_{lw} = -2.9 \pm 0.3$ ), that is, cube, is that normally used to describe wind power, or rate of transfer of energy from wind. If the short wind effect is described in terms of wind power, the results of the analysis to date can be written as

$$r = \text{constant } d_{td} \cdot P_{td}^{-1} P_{tns}^f \cdot s_{tns} \quad (2)$$

in which  $r$  is the dose rate;  $d_{td}$ , the mean discharge rate, over time  $t_d$  fixed by turnover of activity and sediment;  $P_{td}$ , the mean wind power, over similar time  $t_d$ ;  $P_{tns}$ , mean wind power, over time  $t_{ns}$  fixed by local conditions relating to net and sediment;  $f$  is an exponent in the range 0.4-0.7; and  $s_{tns}$  is a measure of air stability, over similar time  $t_{ns}$ .

The indicated time periods are being studied in other experiments in order to separate the parts played by discharge, net and sediment.

Meanwhile at DERE during the past year environmental dose rates have been computed in the laboratory, from Chemical Services and meteorological data, using a slide rule constructed from the three seasons' analysis. The longer term interest of this work lies in the opportunity offered for the study of physical processes in coastal waters.

I thank the staff of DERE for their help in this work; the Ministry of Agriculture, Fisheries and Food and the Scottish Development Department for their support; and Mr J. Preece for his invaluable contributions and computations.

Received June 20, 1967.

## Pleistocene Deposits and New Fossil Localities in Kenya

Bedded rocks near Lake Baringo have yielded a variety of vertebrate fossils, including a right temporal bone with features which suggest that it is an australopithecine or early hominine.

I HAVE been concerned with geological mapping of 400 square miles in the Northern Rift Valley of Kenya. In the process, I have found fossil localities in sediments to the west of Lake Baringo. The sediments, located at  $36^\circ 5' E$ ,  $0^\circ 47' N$ , were first described by Gregory<sup>1</sup>, and later became known as the Kamasia sediments, for they outcrop close to the foothills of the Kamasia Range. Until 1950, however, no fossils useful for dating had been obtained from these sediments.

In 1950, Fuchs<sup>2</sup> described vertebrate remains from a horizon which seems to lie about 60 ft. from the local top of the sediments. These were dated as Pleistocene by Hopwood (in Fuchs<sup>2</sup>), but beneath this faunal horizon is a maximum of 1,000-1,100 ft. of sediments which, until October 1965, had yielded only fossil fish remains (species of *Tilapia* and *Clarias*)<sup>3</sup>. Only recently has it been appreciated that the sediments do not comprise a straightforward, continuous sequence. McCall, Baker and Walsh<sup>3</sup>

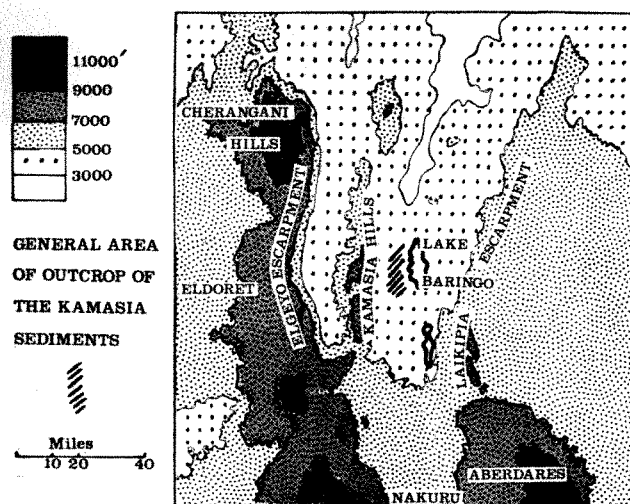

Fig. 1. Position of the area investigated in West Central Kenya.

made it clear that two sedimentary sequences are represented, and that these are separated by a period of lava outpouring, followed by the faulting of these lavas and the underlying sediments. The lower sequence was named the Chemeron Beds<sup>3</sup>, from the Chemeron River section. The upper sediments, which rest unconformably on the lower ones, and their capping lavas, were called the Kapthurin Beds after the nearby Kapthurin River. In October 1965, I recognized the two separate formations, and began to investigate them in detail.

Although this communication is primarily concerned with the lower or Chemeron Beds sequence, the succession of the Kapthurin Beds is summarized here for the sake of completeness. The Kapthurin Beds were deposited largely in a fluvial basin, although outliers of plateau and piedmont gravel occur well outside the main area of sedimentation. The thicknesses given below are the maximum ones, and all the sub-divisions listed die out completely against the lava plateau edges of the basin.

### The Kapthurin Beds

#### *Upper torrent wash* (80')

Unstratified brown earthy silts with gravelly horizons.

#### *Upper tuffs* (up to 40')

Buff coloured fine-grained tuffs well bedded in thick units.

#### *Middle torrent wash* (130')

Brown earthy silts with calcareous conglomerates locally near top. This sub-division has yielded vertebrate remains.

#### *Pumice tuffs* (up to 40' or more)

Coarse terrestrial pumice tuffs with washouts and a variable admixture of torrent wash silts.

#### *Lower torrent wash* (base not often seen, may exceed 150' locally)

Coarse bouldery gravels with brown earthy silts; rests on very uneven surface of lava fault blocks.

### The Lake Hannington Phonolites

Lavas of several different types are seen to overlie the Chemeron beds. Some are true phonolites, though many are trachytes with trachybasalt affinities. Most are doubtless equivalent in the broad sense to the Lake Hannington phonolites of the type area.

### The Chemeron Beds

The succession of the Chemeron beds is given below. The sub-divisions are lithological ones established as a

result of field work carried out by me in October and November 1965.

Upper Tuffs (20–100 ft.)  
Upper Fish Beds (up to 250 ft.)  
Lower Tuffs (9–16 ft.)  
Lower Fish Beds (up to 320 ft.)  
Basal Beds (0–150 ft. or more)

The Basal Beds rest on basalts wherever they are exposed, and they seem to have derived much of their material from the breakdown of these rocks. Much of the basalt was highly decomposed when the Basal Beds began to accumulate. The lavas weather to a soft earthy, gritty product, or in some places to deep red lateritic earths. This weathered material was washed and reworked, and deposited along with accumulations of sand, grit and gravel. Much of the coarser clastic material has its origin in fresher basalt, or occasionally from phonolite of a type now outcropping abundantly in the Kamasia Range to the west.

The Basal Beds accumulated in a depression not more than 5 miles from north to south; thus they are overlapped by the younger Chemeron Beds which extend farther. Although water was involved in deposition, no permanent lake existed in the depression. Impure diatomites and fish-bearing silts are restricted both vertically and horizontally and usually occur high in the Basal Beds. Proboscidean-bearing lithic grits and gravels are characteristic, and represent a fluvial environment. Important proboscidean-yielding sites are at J.M. 91, very close to the absolute base of the beds; J.M. 511, about 35 ft. from the base of the beds; J.M. 513, almost at the base; J.M. 514, close to the top of the Basal Beds. J.M. 511 also yielded hippopotamus remains.

Dr L. S. B. Leakey of the National Museum Centre for Prehistory and Palaeontology, Nairobi, Kenya, has commented as follows on the mammalian fossils from the Basal Beds.

"The proboscidean fauna of the Basal Beds viewed as a whole is strongly suggestive of that from strata attributed to the 'early Villafranchian'. It consists of *Elephas cf. subplanifrons* (J.M. 511), *Elephas cf. africanus* (J.M. 511), *Anancus kenyensis* (J.M. 513) and *Deinotherium cf. bozasi* (J.M. 511 and a juvenile from J.M. 514). Locality J.M. 514 has also yielded the almost complete skeleton of a proboscidean.

"At locality J.M. 91, there is a more highly evolved elephant, probably a derivative of *Elephas africanus* and approaching the early form of *Elephas recki*. Locality J.M. 91 is near the local base of the Basal Beds and has yielded also excellent specimens of a fossil species of *Papio* comprising a skull and also a nearly complete skull and skeleton.

"Remains of a large rhinoceros have been found at two localities, J.M. 91 (Basal Beds) and J.M. 507 (Lower Fish Beds). They resemble *Serengeticerus*, but exact determination is not yet possible and must await the revision of all East African Pleistocene Rhinocerotidae which will be carried out soon.

"Hippopotamus remains have been found in the Basal Beds (Localities J.M. 511, 512) and the Lower Fish Beds (Localities J.M. 106, 507). Both hexaprotodont and tetraprotodont forms are represented. This group is undergoing a major revision, after which specific identification of some of the material should be possible."

The Fish Beds comprise the bulk of the Chemeron Beds succession. They seem to be almost entirely lacustrine and fluvial; fish remains are abundant. A prominent tuff horizon has been used to divide the succession into an upper and a lower group, and this horizon has proved to be persistent over most of the area of outcrop examined.

The transition at the top of the Basal Beds into the lithology of the Lower Fish Beds marks the oncoming of a wholly lacustrine environment. The basin of deposition manifest in the distribution and thickness of the group shows a gradual expansion through the period of deposition of the group. A maximum thickness in the region of

320 ft. was measured in a tributary of the Kapthurin River, although this figure may be amplified further in a southerly direction because of the presence of grits and gravels locally.

Although lavas and tuffs were the parents of much of the sediment, the beds represent washed and sorted materials of fine texture. Diatomite units as much as 40 ft. thick illustrate slow or negligible deposition of clastic fragments. Tuffaceous grits and lava derived gravels are not common except in the Ndaui River area. Northward and southward thinning of the sub-division is evident, although there are no important changes in lithology. The observed north-south extent of the basin had increased to about 10 miles.

Fossil remains are quite common in the Lower Fish Beds; fish remains are particularly abundant, especially forms resembling species of *Tilapia* and *Clarias*. Thin ironshot sands and grits often contain abundant fish remains as well as occasional teeth of crocodiles. While such horizons indicate slow accumulation in shallow water, well-defined breaks in the sequence are rare. One particularly interesting exposure (J.M. 106) displays a thin grey clay resting on the eroded surface of a tuffaceous sandstone. The clay yielded the mandible of a hippopotamus associated with parts of the base of the skull. This particular horizon is believed to lie not more than 30 or 40 ft. from the base of the Lower Fish Beds. Another hippopotamus locality, J.M. 507, is at a similar position in the sequence.

The Lower Tuffs form a useful marker horizon separating the silty Lower Fish Beds from the more gravelly Upper Fish Beds. It is a primary tuff, and so this unit is a time plane. The light pumiceous ash was deposited under water, and the fine bands show the delicate current structures often seen in silts.

The Lower Tuffs came at a time when the southern part of the lake basin was about to become inundated with coarse clastics; thus in many places they emphasize a realistic dividing plane from the Upper Fish Beds. Evidence of cross bedding and general distribution of coarse clastics suggests that material was carried into the basin from the west in the southern part of the area. The successions in the Barsemoi, Ndaui and Chemeron Rivers thus contain gravels and sands deposited on a fluvial plain, as well as lacustrine silts containing fish remains. While an important pebble bed persists through the Kapthurin River section, and into unexposed country to the north, fine silts and diatomites become more important northwards. Probably the thin diatomaceous silts and diatomites persisting in the extreme north of the outcrop belong with the Upper Fish Beds, so that the lake basin extended to a maximum during this period.

Fish remains are well distributed and reasonably abundant, except in the gravels. Molluscs also lived in the lake, and locally their remains accumulated to form shelly limestones. It is the mammalian fossils which are most interesting, however, and these include a hominid temporal discovered in October 1965 by John Kimengich. The fossil was found weathered out on the surface of an exposure of the Upper Fish Beds at J.M. 85 in a small tributary of the Kapthurin River (Fig. 2). The specimen was initially identified as a hominid fragment by Mr Jonathan Leakey. There is little doubt that the fossil came from the Upper Fish Beds and not from a higher horizon in the Chemeron Beds or from the unconformable veneer of gravel capping the surrounding plateau. The surface of the exposure where the hominid was found is almost a bedding plane slope, and follows the strike very closely for short distances upstream and downstream. The specimen had fragments of lithic grit clinging to it when found, and this sediment matches the lithology of some lenses of calcareous lithic grit distributed through the lowest 16 ft. of the Upper Fish Beds. The most likely source of the hominid fragment is in a very thin grit band about 8 ft. from the base of the Upper Fish Beds.

Fig. 2. Cross section of the hominid site, looking northwards. (a) Silts of Lower Fish Beds. (b) Lower Tuffs—coarse and fine waterlain pumice tuffs at a depth of 16 ft. (c) Buff coloured silts with bands and lenses of calcareous, lithic grit, some of which was found adhering to the hominid fragment. Fish remains are abundant in the silts at a depth of 16 ft. (d) Finer silts and light coloured tuffs. Both (c) and (d) belong to the Upper Fish Beds.

Dr Leakey has commented on the age suggested for the beds yielding the hominid fragment by the mammalian fauna obtained so far from the Chemeron Beds. "The lack of good mammalian fauna from the Upper Fish Beds, on the surface of which the fossil hominid temporal was found, precludes direct faunal dating of this deposit at present. It clearly overlies the lower members of the Chemeron Beds which yielded the mammalian fauna of 'early Villafranchian' aspect. It is unconformably overlain by the Kapthurin Beds which contain an advanced Acheulian industry in their upper levels."

Professor P. V. Tobias of the Department of Anatomy, University of the Witwatersrand, Johannesburg, has examined this temporal bone, and has commented on it (succeeding communication).

The Upper Tuffs are widespread, although so far they have yielded no fossils. Stratified and waterlain, they herald the extrusion of the Lake Hannington Phonolites, which terminated lacustrine conditions in the area in question. Earth movements after the Lake Hannington Phonolites had the effect of breaking the rocks up into tilted blocks bounded by closely spaced faults. This has complicated the picture somewhat and has made interpretation of the deposits difficult, because nowhere does one find a straightforward sequence unaffected by faulting.

The earth movements renewed the movements along faults bounding the Kamasia Range, and this led to rejuvenation of erosion followed by the submergence of large tracts of country beneath plateau gravels. The Kapthurin Beds accumulated in a basin, and in doing so buried a large part of the outcrop of the Chemeron Beds. The latter have now been only partly re-exposed by present day rivers.

Examination of the Chemeron Beds, and their possible equivalents elsewhere in the area, has yet to be completed. It is certain that a great deal of fossil material has yet to be discovered from these and other deposits in the Baringo area.

I hold a studentship from the Natural Environment Research Council and am engaged in a research project under the direction of Professor B. C. King. The project is primarily concerned with the geological mapping of an area of some 6,000 square miles in the northern Rift Valley of Kenya and is being undertaken with the co-operation of the Geological Survey of Kenya and in association with the Geology Department of University College, Nairobi. The project is financed jointly by the Ministry of Overseas Development and the Government of the Republic of Kenya. I thank Dr and Mrs L. S. B. Leakey

and Mr R. E. Leakey of Nairobi; Professor P. V. Tobias of the University of Witwatersrand; Professor B. C. King and Dr W. W. Bishop of the Geology Department, Bedford College, for advice, and Mr and Mrs J. H. E. Leakey of Kampi-Ya-Samaki, Kenya; Mr J. Walsh of the Geological Survey of Kenya; Mr L. A. J. Williams of the Geology Department, University College, Nairobi; and Messrs John Kimengich and Malakwen Cheptoo, who located many fossils.

JOHN MARTYN

Department of Geology,  
Bedford College,  
University of London.

Received January 11; revised June 6, 1967.

<sup>1</sup> Gregory, J. W., *The Rift Valleys and Geology of East Africa* (Seeley Service and Co., London, 1921).

<sup>2</sup> Fuchs, V. E., *Geol. Mag.*, **87**, 149 (1950).

<sup>3</sup> McCall, G. J. H., Baker, B. H., and Walsh, J., *Background to Evolution in Africa* (edit. by Bishop, W. W., and Clark, J. D.) (University of Chicago Press, 1967).

THE specimen found by John Martyn comprises most of the right temporal bone and includes a number of diagnostically useful regions, notably the mandibular (or glenoid) fossa, the tympanic bone and external acoustic meatus, part of the mastoid process and the supramastoid crest, the root of the zygoma, and most of the petrous pyramid. Close examination suggests that the specimen should be assigned either to the genus *Australopithecus* or to a lowly hominine taxon, but the exact genus and species cannot be identified on this temporal bone alone.

The mandibular fossa is very long and wide, but absolutely and relatively shallow. The dimensions have been determined using landmarks and definitions given by Weidenreich<sup>1</sup>. The values obtained and the derived indices are given in Table 1, where they are compared with values for other hominoids. I obtained the values for australopithecines and for Old.H13 on the original specimens; the values for hominines and pongids are quoted from Weidenreich (op. cit., Table X, page 46). In absolute length (26.7), the Chemeron mandibular fossa fits within the sample ranges for *Australopithecus* and for *Homo erectus*. The absolute breadth of the Chemeron fossa is somewhat greater than in the australopithecine sample, with the exception of one of the Old.H5 (*Zinjanthropus*) fossae (Fig. 2), and exceeds the upper limit of the *H. erectus* sample by 1.8 mm. The difficulty of determining absolute landmarks for these measurements means that the length and breadth of the Chemeron mandibular fossa cannot be differentiated from those of the available samples of either *Australopithecus* or *H. erectus*; this holds as well for the L/B index.

Absolute depth can be determined with more precision. The sample ranges for *Australopithecus* (7.5–10.0) and for

Fig. 1. The Chemeron hominid temporal bone. (A) Lateral aspect; (B) medial aspect; (C) inferior aspect; (D) superior aspect. (1) Mastoid crest; (2) temporal squame; (3) root of zygoma; (4) grooves for middle meningeal artery; (5) sulcus for sigmoid sinus; (6) petrous pyramid; (7) postglenoid process; (8) anterior wall of mandibular fossa; (9) pre-glenoid plane; (10) entoglenoid lip; (11) downturned edge of tegment tympani; (12) auriculare.

*H. erectus* (11.5–18) do not overlap; the fossa in the former hominid is absolutely and relatively shallower<sup>2,3</sup>. The value in Chemeron (10.6) lies between the two quoted sample ranges, but nearer to that for *Australopithecus*. The same is true of the D/L index which distinguishes fairly sharply between the australopithecine and *H. erectus* samples, while the Chemeron D/B index falls within the sample range for *Australopithecus*. The fossae of *H. erectus* and *H. sapiens* differ from those of the australopithecines and pongids principally in their greater absolute and relative depth. Ashton and Zuckerman<sup>4</sup> have shown that the hominine mandibular fossa is usually anteroposteriorly "compressed", that is, deeper and shorter than in pongids. This "compression" of the fossa is not apparent in australopithecines, although in a number of other respects the fossa in this group departs from the pongid pattern<sup>5</sup>. The Chemeron mandibular fossa agrees with those of the australopithecines in not showing such "compression"; but so does that of the Olduvai Bed II hominine represented by the specimen

Table 1. DIMENSIONS AND INDICES OF THE MANDIBULAR FOSSA IN THE CHERMERON TEMPORAL COMPARED WITH THOSE OF OTHER HOMINIDS

	Length	Breadth	Depth	L/B%	D/L%	D/B%
Chemeron (R)	26.7	35.7	10.6	74.8	39.7	29.7
Olduvai Hom 13	18.0	About 22.5	About 8.0	About 80.0	About 44.4	About 35.5
<i>A. africanus</i> (MLD 37/38)	22.3–23.1	29.3–31.6	7.5–8.0	73.1–76.1	32.5–35.9	23.7–27.3
<i>A. robustus</i> (2)	25.2–28.1	31.4–32.4	9.0–10.0	77.8–89.2	35.6–36.0	27.8–31.7
<i>A. boisei</i> (Old.H5)	27.6–27.9	32.9–35.9	8.5–8.8	76.9–84.8	30.8–31.5	23.7–26.7
Total <i>Australopithecus</i> (7 fossae, 4 skulls)	22.3–28.1	29.3–35.9	7.5–10.0	73.1–89.2	30.8–36.0	23.7–31.7
<i>H. erectus pekinensis</i> (5 fossae, 4 skulls)	16–21	23–27	11.5–15.0	72.0–78.3	63.8–83.2	46.0–65.2
<i>H. erectus erectus</i> (2 skulls)	28	23–28	13–18	100–123	46.4–64.3	56.5–64.3
Old.H9	22	34.1	13	64.5	59.1	38.1
Total <i>H. erectus</i> (7 skulls)	16–28	23–34.1	11.5–18	64.5–123	46.4–83.2	38.1–65.2
<i>H. sapiens</i> *	23.0–27.0	21.5–26.0	12.5–16.5	88.4–109.5	53.2–69.5	58.2–63.4

Orang-utan (male)†	18	40	9	45.0	50.0	22.5

\* Ranges of population means.

† Sample means.

officially catalogued as Old.H13 (ref. 4), and included originally as a paratype of *H. habilis*<sup>5</sup>. The teeth and jaws of Old.H13 were recognized later to be more hominine in character than those of the Bed I type specimen of *H. habilis*<sup>6</sup> and some people have "allocated" Old.H13 as a whole to *H. erectus*. While not yet committing myself on the final taxonomic designation of the Old.H13, it seems to be commonly accepted that it is a hominine and not an australopithecine. But it does not show as marked a degree of anteroposterior "compression" of the fossa as in *H. erectus* and other hominines (Table 1). Thus its D/L and D/B indices (44.4 and 35.5) fall in between the sample ranges for *Australopithecus* and *H. erectus* and exceed those of Chemeron (39.7 and 29.7) by only 4.7 and 5.8 respectively. Thus although in absolute size the fossa of the adolescent female Old.H13 is smaller, it indicates that—on the depth of the fossa—we cannot exclude the possibility that the Chemeron temporal belonged to a lowly hominine.

The anterior wall of the mandibular fossa (Fig. 1C) has a threefold curvature typical of australopithecines and some early hominines: it is strongly concave mediolaterally, it slopes downwards and forwards at an angle of about 45° to the estimated plane of the Frankfurt horizontal, and it slopes from anterolateral to posteromedial. The postglenoid process is small, compressed and uninflated, and it furnishes a very small part of the posterior articular surface of the glenoid fossa (Fig. 2). Most of the posterior articular surface is formed by the nearly vertical anterior face of the tympanic, as in most australopithecines, Old.H13 and hominines, but unlike the arrangement in pongids. The medial boundary (Fig. 1C) is not a distinct entoglenoid process as in *A. boisei*, but simply the downturned medial margin of the squamosal, as in some australopithecines, and Old.H13. The sphenosquamosal suture is not preserved and it is therefore impossible to see whether the alisphenoid contributes to the entoglenoid wall as in *A. africanus* and Old.H13. Thus the overall features of the mandibular fossa have much in common with those of the australopithecines, as well as those of some lowly hominines, and do not therefore help in the determination of the exact taxonomic affinities of the specimen.

Fig. 2. The Chemeron temporal compared with that of *Australopithecus (Zinjanthropus) boisei*. Note the delicate entoglenoid lip of Chemeron, contrasting with the bulbous entoglenoid process of *A. boisei*; contrast, too, the compressed postglenoid process of Chemeron with the somewhat inflated process of *A. boisei*.

The external acoustic porus is large (12.5 × 10.0 mm), circular to oval with its long axis almost vertical, a thin tympanic rim thickened below and behind with a small notch between the two thickenings (Fig. 1A). There is a distinct suprimeatal spine. These features of the porus are clearly hominid rather than pongid, and closely resemble those of the original Kromdraai *A. robustus* specimen<sup>7</sup>. The plane of the porus is set almost flush

with the auricular point, as in Kromdraai, skull 8 from Sterkfontein<sup>7,8</sup>, and Old.H13, and there is little projection of the posterior root of the zygoma above the ear-hole. In this respect, Chemeron contrasts strongly with *A. boisei* and *H. erectus* with their massive shelf-like projections<sup>2</sup>, and resembles more closely *A. africanus*.

Although it was partly broken, enough of the mastoid process was preserved to indicate that it projected strongly on the side of the base of the skull (Fig. 1C and D), as in australopithecines, far exceeding in degree the projection on *H. erectus* crania, even including the massive cranium from LLK Olduvai (Old.H9, formerly called "Chellean Man").

The petrous part (Fig. 1D) has a nearly vertical posterior face and detailed morphology as in hominids<sup>9</sup>. The superior margin is a sharp edge which partly overlaps the posterior surface, as in Old.H5 (*A. boisei*), Sts 5 (*A. africanus*) and modern man; it contrasts with the blunt, rounded border in *H. erectus* including Old.H9.

The root of the zygomatic process (Fig. 1D) is very broad (about 34 mm long), slopes fairly steeply downwards towards the preglenoid plane and has a faint hollow, the sulcus processus zygomatici, on its antero-superior surface. It resembles the corresponding feature in both *Australopithecus* and *H. erectus*.

Although the supramastoid crest is interrupted by small areas of damage and by marked vascular grooves (presumably for the middle temporal artery and perhaps the deep temporal arteries), it is clearly a poorly developed feature, resulting in a marked hollow on the side of the cranium between the mastoid process behind the zygoma in front (Fig. 1D). This feature reproduces the structure found in *A. africanus* and in modern man.

The broken mastoid process and upper edge of the squame indicate a considerable degree of pneumatization, as in all early hominid crania, but not as marked as in the very heavily pneumatized cranium of *A. boisei*, nor probably as in the crania of *A. robustus* and *H. erectus*<sup>3</sup>.

Most of the features of the Chemeron temporal suggest that it belonged to an australopithecine. The only feature suggesting an affinity with *A. boisei* is the large size of the mandibular fossa; in other respects, the Chemeron specimen resembles more closely *A. robustus* and *A. africanus*. A good proportion of its traits, however, are compatible with lowly hominine status, some suggesting a closer affinity with an evolved *H. habilis* (Old.H13), others with *H. erectus*. On the evidence of this temporal bone alone, it is impossible to assign the specimen firmly to either of the most widely recognized Pleistocene genera of the Hominidae, *Australopithecus* or *Homo*. Until more material is recovered, the form represented by the temporal is identified as follows:

Family: Hominidae  
Gen. et spec. indet.

I thank the US National Science Foundation and the University of the Witwatersrand, who made it possible for me to study the specimen; and Dr L. S. B. Leakey, Professor B. C. King, Mrs. T. Hitchings, A. R. Hughes and R. Campbell for assistance.

# Mechanism of Biological Memory

by  
L. B. MEKLER

Ivanovsky Institute of Virology,  
USSR Academy of Medical Sciences,  
Moscow

General mechanism for brain memory and immunological memory is proposed. Immunological memory could involve the transfer of information for the synthesis of the active site of an antibody, by an antigen-RNA complex, to a potentially immune cell. This transfer would involve the reversal of the path of information from DNA to RNA to protein which occurs during protein synthesis.

THERE are known to be three types of biological memory: (a) genetic memory, the discovery and unravelling of which has been due to molecular biology; (b) conventional memory, which is a function of the brain; and (c) immunological memory. In spite of the apparent differences between these types of memory they probably have much in common, and presumably a single mechanism is responsible for the working of all three. Any signal received by the nervous system from external media for a time sufficient for the brain to memorize it is thought to be converted to structural change<sup>1-7</sup>. This means that the brain memory, like genetic and immunological memory, is dependent on the formation of tangible structures which are responsible for the existence and content of the memory.

There is disagreement when an attempt is made to determine the position, chemical nature, and initiating and fixing mechanism of the suggested structural changes<sup>1-7</sup>. It is interesting that, as with immunological memory, two contrasting points of view have been voiced to explain the essence of brain memory. The first suggests that the sum of information which is finally fixed by the brain is contained in the body itself, for example in DNA, and that the signal only serves to select the information<sup>6,7</sup>. This is in principle analogous to the theories of immunological memory of Burnet<sup>8</sup> and Szilard<sup>9</sup>. The second point of view is based on the assumption that the role of the signal is not selection but formation of a particular structure<sup>5,10</sup>, which coincides in principle with the theories of immunological memory put forward by Haurowitz<sup>11,12</sup> and Pauling<sup>13</sup>. But there may be a third point of view which is to a certain extent a product of the two previous ones<sup>6-13</sup>, although they appear to be mutually exclusive. This third approach permits an explanation of the general nature of all types of biological memory.

A signal is fixed by the appropriate receptor and is transmitted from neurone to neurone by means of a certain chemical mediator. This substance reacts with the neuronal membrane, that is, with a certain protein causing a chain of reactions which lead to a certain action. It is, however, established that the reaction of the small molecule with the protein can cause a change in the conformation of the protein. This takes place, for example, during the interaction of oxygen or carbon monoxide with haemoglobin, when the change in conformation is so evident that it is recorded both by changes in the crystal formation of the protein and by X-ray photography<sup>14</sup>. I assume that the structural change obtaining while an event is being memorized is the result of a change in protein conformation. Although the number of proteins which the body can synthesize as a result of the genetic information contained in its DNA is large, it is, nevertheless, limited and is smaller than the enormous stream of information which the organism is capable of receiving and memorizing. Accepting this assumption I conclude that one of the brain's memory links is the emergence of a protein with a new conformation, formerly not peculiar

to the organism in question. In immunological terminology this newly emerged information can be described as a new antigenic structure of the particular protein's surface. This new antigenic structure has obviously emerged as a result of a certain signal to which the organism reacted in a definite manner. This means that the presence of the particular protein molecule with a particular item of information predetermines the possibility of a specific response if the information is preserved in time, that is, memorized by the organism. It is therefore essential to determine how the organism retains the information of a particular protein conformation for a prolonged period of time. It is well known that proteins, including the structural proteins of the organism, disintegrate rather rapidly within the organism. The shortest half-life of the total brain protein is 2.2 days<sup>15</sup>, and the appearance of the new protein conformation in response to the signal is not reflected in the genetic code of phylogenetic origin. It is necessary to determine how the organism can memorize the information of the new antigenic structure, a task which is analogous to the problem of immunological memory.

The subject of immunological memory has been elaborated much more theoretically and experimentally than has that of memory, which is a function of the brain. It is, however, far from fully understood. The mechanism of immunological memory as it is known consists of the biosynthesis of antibodies and the formation of immune lymphocytes. It is impossible here to discuss all aspects of the classical theories<sup>16</sup>, but I must point out that the principal difficulty of the instructive theory is its inability to explain the complexity of immunological phenomena which result from the functions of the immune lymphocytes; the theory also involves a biosynthesis of antibodies which runs counter to all modern conceptions of the biosynthesis of proteins. A weakness of the clonal selection and mutation-genetic theories is their inability to explain the organism's ability to produce antibodies for the synthetic antigenic determinants, and the inability of haptens, which bind with the active centre of the antibody like the substrate with the enzyme, to induce biosynthesis of antibodies.

I hope that my hypothesis will make it possible to solve the difficulties referred to here in connexion with the immunological memory theory, and serve to describe a process which explains the mechanism of biological memory as a whole. For the sake of simplicity I first examine how this hypothesis explains the formation of an antibody active site in response to an antigen introduced into the body. If a foreign protein is introduced into the body, the response is a quantity of antibodies, all of which react with their specific antigenic determinants. The antigenic determinant is either a section of polypeptide consisting of six to ten amino-acid residues, or a section of polysaccharide consisting of approximately six monose residues, or of a similar but more complex structure consisting of amino-acid residues, sugars and lipids<sup>17</sup>.

Fig. 1. A schematic representation of the antigenic determinant and the antibody active site, and the dislocation of their functional groups in the antigen-antibody complex.

The antigenic determinant can thus be schematically conceived as a chain of linearly arranged recurring bonds, such as peptide bonds, perpendicular to which are the side groups of, for example, carbon chains of amino-acid residues, which as a whole determine the specificity of the particular antigenic determinant (Fig. 1).

An analogous scheme may describe the structure of the antibody active site, which is also a section of a polypeptide chain. The link between the antigen and its respective antibody and its unusual strength is explained by their conformity to one another, that is, their complementarity to one another. This is shown schematically in Fig. 1, where the residues of amino-acids of the antigenic determinant peptide chain complement the amino-acid residues of the peptide chain of the antibody active site. This conformity probably permits the binding of a given number of chemical groups of the antigenic determinant (the van der Waals bonds, the hydrogen bonds, the hydrophobic and heteropolar bonds) which Pauling considers to be the basis of the exceptional strength of the bond which results from the antigen-antibody reaction. This is known to be a purely physico-chemical process and is subordinated to the law of mass action. The latter is confirmed experimentally by hapten inhibition of the antigen-antibody reaction<sup>17</sup>.

Consider a situation in which the biological mechanism of protein synthesis is unknown, and the antibody active site to a given antigenic determinant is to be synthesized by physico-chemical means. The active site of the antibody is known to consist of amino-acid residues, but the identity of the amino-acids which should be taken to build a peptide chain with the properties of the antibody active site to the given antigenic determinant is not known. There is, however, a single set of amino-acids which is determined by the structure of the antigenic determinant itself, which can therefore make the selection itself. Thus a single antigenic determinant can be introduced into the solution; this adds to the solution the twenty amino-acids which constitute all proteins. Like the antigen-antibody and the hapten-antibody reactions, this particular synthetic system should obey the law of mass action<sup>18</sup>, which means that some of the twenty amino-acids added may spontaneously orientate themselves around the antigenic determinant. These will be those amino-acids which can ensure a sum bond of maximum firmness, that is, those which store the most energy (Fig. 2). The rest of the amino-acids will remain in solution.

This unfortunately is as far as an attempt to synthesize the active site of the antibody can be taken, for it is well known that peptide bonds are not formed spontaneously. Nevertheless, in the normal conditions of life, during the biosynthesis of the protein, it is not free amino-acids which are employed in the cell but their complexes with the appropriate transport RNA. It will not therefore be amino-acids, complementary to the antigenic determinant, which orientate themselves around the latter, but it will be the amino-acids complexed with their respective

tRNA, similar to the situation in Fig. 2. The chief significance of this scheme is the fact that the structure of the antigenic determinant is thus translated into the language of a nucleotide sequence, based on the inherent ability of every tRNA to link up only with a definite amino-acid. But this kind of structure, although it bears the information recorded in the nucleotide code, necessary for the synthesis of the active site of the antibody, is unstable and can hardly serve as a basis for a consecutive synthesis of the active site of the antibody. There must be a process which stabilizes the emerging sequence of nucleotides.

The second part of my hypothesis of the mechanism of the biological memory is the assumption that this process consists of the synthesis of mRNA on a template of orientated tRNA from which appears a stabilized polynucleotide structure. This means that in nature information is transmitted not only in the direction of DNA to RNA to protein, but also in the opposite direction, that is, protein to RNA to DNA. It has been shown experimentally that half of the postulated information transmission is in the direction from protein to DNA<sup>19,20</sup>.

The process described here is a hypothetical scheme for the translation of information contained in the protein into the language of the nucleotide sequence, but it does not describe the manner in which the organism synthesizes antibodies from the various fragments of peptide chains<sup>21</sup>, nor the manner of the formation of immune lymphocytes. I have discussed here only the synthesis of the active site of the antibody the structural dependence of which on DNA has not yet been shown<sup>21</sup>, unlike other peptide fragments from which antibodies are synthesized by some unknown mechanism. The particular mechanism behind this process constitutes the third part of the hypothesis of biological memory, the substance of which is as follows.

The three layered structure shown in Fig. 2, consisting of an antigenic determinant, the antibody active site, and a corresponding mRNA, has a kind of lineal dimension. For clarity and simplicity of discussion this ribbon-like arrangement can be wound around the position of the mRNA. The result will be a ball, as shown in Fig. 3. It is easy to see that this ball is designed like a virus, with mRNA in the centre bearing the genetic information necessary for the synthesis of one of its membranes, in this case analogous to the complex of antibody active sites.

When such a "virus" penetrates a sensitive cell, as was suggested<sup>22</sup>, and later confirmed experimentally<sup>23</sup>, the viruses of the second and fourth groups of the classified types of virus-cell interaction<sup>22,23</sup> are capable of trans-

Fig. 2. A schematic representation of the orientation of amino-acid and tRNA complexes, and mRNA synthesis on tRNA-template.

Fig. 3. A schematic representation of the virus-like particle carrying information (*mRNA*) for the synthesis of the antibody active site and transmitting it from the macrophage to the immuno-competent cell.

forming the cell membrane into an immunological structure identical to that of the virus, that is, genetically determined by the virus RNA. In this case if the "virus" described here penetrates the cell which will eventually become a lymphocyte, it can, in accordance with the second type of virus-cell interaction, convert the lymphocyte cell membrane into a structure, genetically determined by the *mRNA* of our "virus", that is, into a structure equal to the active site of the antibody. This signifies that the lymphocyte will become immune with respect to the antigen, which evoked the formation of the *mRNA* of the "virus". The lymphocyte thus transformed will simultaneously be able to synthesize a certain amount of humoral antibodies consisting of "virus" and fragments determined by cell DNA, just as when, for example, during the replication of the influenza virus, capsides of the virus membrane synthesized on the cell ribosomes are determined by the influenza virus RNA as well as by the cell DNA<sup>22,24</sup>. Should such a virus, on the other hand, enter a cell which will later become plasmatic with a ramified ribosome network, then the process will be a synthesis of humoral antibodies, like the synthesis of the influenza virus membrane capsid on the cell ribosomes.

It should be emphasized here that according to my hypothesis the antibody consists of the principal part of the molecule, the structure of which is determined by the DNA of the organism and the active site, the structure of which is determined by the antigen. It is because of this structural and genetic heterogeneity, and in spite of the suggested mechanism of reversed transmission of information, that the immunization of, say, mice with rabbit antibodies to albumin does not evoke the formation of a whole molecule of albumin. It evokes instead only the biosynthesis of a composite group of mice antibodies, each one of which may be the bearer of a locus peculiar to the initial albumin. Conversely, when the reversal of the transmission of information in the neurone is initiated by the new antigenic structure, a product of the mediator, the formation of an active site of the "antibody" should be followed by the formation of a structure complementary to the "active site", resulting in the formation of a double membrane. These double membranes of the cell are therefore by my hypothesis complementary structures, as if constituting continuous rows of antigenic determinants and antibody active sites, forming an internal and external surface of the cell membrane respectively.

It is, however, necessary to explain the conditions in which the entry of the protein into the cell will evoke a reversal of transmission of information and when it will not. The fourth part of my hypothesis of the mechanism of biological memory is the assumption that the transmission of information is reversed when a protein is produced in or penetrates into the cell without the appropriate *mRNA*. The entry of protein is blocked if the *mRNA* is present. If it is a foreign protein and there is therefore no appropriate *mRNA* in the cell, reversal commences.

It must be pointed out that the mechanism of immunological memory described here agrees with the latest

experimental data concerning antibody biosynthesis. This has been shown to occur in two stages. After the macrophage has consumed the antigen a complex of antigen and RNA (according to this scheme corresponding to stage 1 in Fig. 4) appears in the macrophage. This complex is eventually ejected from the macrophage and bears the information necessary for the synthesis of the active site of the antibody in another cell, say, one which is turning plasmatic, and in which the antibody will then be synthesized (the second stage in this scheme, Fig. 4) (refs. 25-30). It has been proved further that the surface of the immune lymphocyte actually reacts to a corresponding antigen just as the cell membrane of a cell infected with the influenza virus undergoes a virus-like transformation of its structure, and begins to react with the red blood cells in the haemo-absorption reaction in a manner similar to the reaction in which the virus agglutinates the red blood cells.

This mechanism of biological memory also agrees with available experimental data, scarce as it is, concerning the processes taking place in the brain during memorization. Part of my hypothesis supports the conceptions of Hyden<sup>5,10</sup> which are based on the accumulation of RNA in the functioning neurones<sup>5</sup>, which he discovered. My mechanism of biological memory also facilitates understanding of why the injection of actinomycin *D* interferes with the formation of a long-time memory, which is, according to my hypothesis, the consequence of a synthesis of appropriate *mRNA*. This synthesis makes permanent the reversal changes of the membrane structure, and does not interfere with the formation of a short-term memory, which from the point of view of my hypothesis is equal to a reversal of conformation of the protein structures of the neurone membrane<sup>7</sup>.

Fig. 4. A schematic representation of the transformation of the intact immuno-competent cell in the immuno-lymphocyte.

It is also made clear why the anatomy of the brain, unlike that of any other organ, precludes the entry of brain antigens into the blood and further into the lymphoid system<sup>31</sup>. This anatomy and functional property of the brain is essential to my hypothesis, for otherwise the newly formed antigens on the surface of the neurone would pass into the blood during the disintegration of the membrane and would cause autoimmune diseases. Evidence of the presence of DNA in the cytoplasmatic membrane, and of the autonomous synthesis of the cytoplasmatic membrane from the DNA nucleus<sup>32</sup>, is essential to my hypothesis. It makes possible an understanding of the dual nature of all biological membranes, and emphasizes the universality of the complementary principle, that is, it confirms its validity not only with regard to nucleic acid but to the protein structures of the membrane type as well. The complementary nature of the antibody active site to the antigenic determinant is only an individual case, a local reproduction of a pheno-

menon which is characteristic of the double membrane in its entirety.

I thank Academician I. L. Knunyants and Professors L. A. Blumenfeld, L. N. Fontalin, A. Ja. Fridenstein, A. E. Gurvich, F. Z. Meerson, Sh. D. Moshkowsky, R. V. Petrov, V. S. Shapot, V. M. Zhdanov and Dr Yr. S. Moshkowsky for their criticism and advice.

## Spermadsorption and Spermagglutination by Mycoplasmas

by

D. TAYLOR-ROBINSON

R. J. MANCHEE

MRC Common Cold Research Unit,  
Harvard Hospital,  
Salisbury, Wiltshire

Adsorption of bovine and human spermatozoa to colonies of mycoplasmas has been demonstrated, as well as spermagglutination by an avian mycoplasma. These phenomena show some similarity to haemadsorption and haemagglutination by mycoplasmas.

CHU<sup>1</sup> observed that bovine and rooster spermatozoa were adsorbed to tissue culture cells infected with influenza and Newcastle disease viruses and, furthermore, that the viruses agglutinated the spermatozoa. Peleg and Ianculescu have made similar observations<sup>2</sup>: adsorption and agglutination of spermatozoa closely paralleled the phenomenon observed with erythrocytes and spermagglutination and haemagglutination titres were similar. The adsorption and adherence of erythrocytes to the surface of *Mycoplasma pneumoniae* colonies on solid agar medium were first observed by Del Guidice and Pavia<sup>3</sup>. Haemagglutination by a mycoplasma was first demonstrated by Van Herick and Eaton<sup>4</sup> and is a prominent feature of mycoplasmas isolated from birds, although it and haemadsorption both occur with certain strains of mycoplasmas isolated from several animal species<sup>5</sup>. It seemed likely that spermatozoa could adsorb to mycoplasma colonies or be agglutinated by mycoplasmas, and we have shown that this is so in experiments reported here.

Our experimental details for spermadsorption are outlined in Fig. 1. Samples of semen from one bull and two humans were used. Motility was assessed after diluting semen in phosphate buffer-saline (PBS) at 37° C so that individual spermatozoa could be observed. The proportion of motile spermatozoa was obtained by comparing the count of motile spermatozoa with the total count of non-motile spermatozoa after the addition of a drop of mercuric chloride. Viability was assessed by mixing one part of semen with ten parts of nigrosine-eosin stain, holding the suspension at room temperature for 5 min and then making a slide smear. The proportion of viable spermatozoa was obtained by comparing the number of unstained spermatozoa with the total of unstained and stained spermatozoa. The preparation and storage of erythrocyte suspensions have been described in detail previously<sup>6</sup>. For spermagglutination and haemagglutination tests, *M.*

*gallisepticum* (A514) adherent to the surface of 'Pyrex' bottles was used as antigen. The adherent sheet was washed three times with PBS, pH 7.2, scraped into a small volume of PBS, dispersed by pipetting and frozen at -20° C until used.

Haemadsorption is a striking property of *M. pneumoniae* and *M. gallisepticum* colonies on agar, and so we carried out preliminary spermadsorption experiments with these mycoplasmas. Suspensions of human and bovine spermatozoa were added in 2.0 ml. quantities to colonies which had recently developed and these cultures were incubated at 37° C for up to 30 min. After this time the heads of many spermatozoa had adhered to the surface and edge of the colonies (Fig. 2). The tails of spermatozoa whose heads were adherent to the edge of a colony were the most easily observed because they lay radially to the colony and moved rhythmically and rapidly over translucent agar. The adherence of both bovine and human spermatozoa was easily seen, although the use of bovine spermatozoa was an advantage in this respect because of their larger size. Spermatozoa suspended in PBS, pH 7.2, adsorbed just as well as those in phosphate buffer, pH 6.0, and the former diluent was usually used. Unwashed human spermatozoa adsorbed just as well as washed spermatozoa, and this was also true for bovine spermatozoa with semen diluted twenty-fold, except in one instance when washed spermatozoa adsorbed more rapidly and extensively.

In a previous study<sup>6</sup> adsorption of erythrocytes to colonies of various mycoplasmas did not occur when colonies were crowded on the agar surface. The possible occurrence of this phenomenon with spermatozoa was investigated. Ten-fold serial dilutions of a suspension of *M. pneumoniae* were inoculated on agar so that a decreasing number of colonies from approximately 10<sup>6</sup> to 10 developed on incubation. Human spermatozoa were added to the series of agar cultures and, for comparison, human group

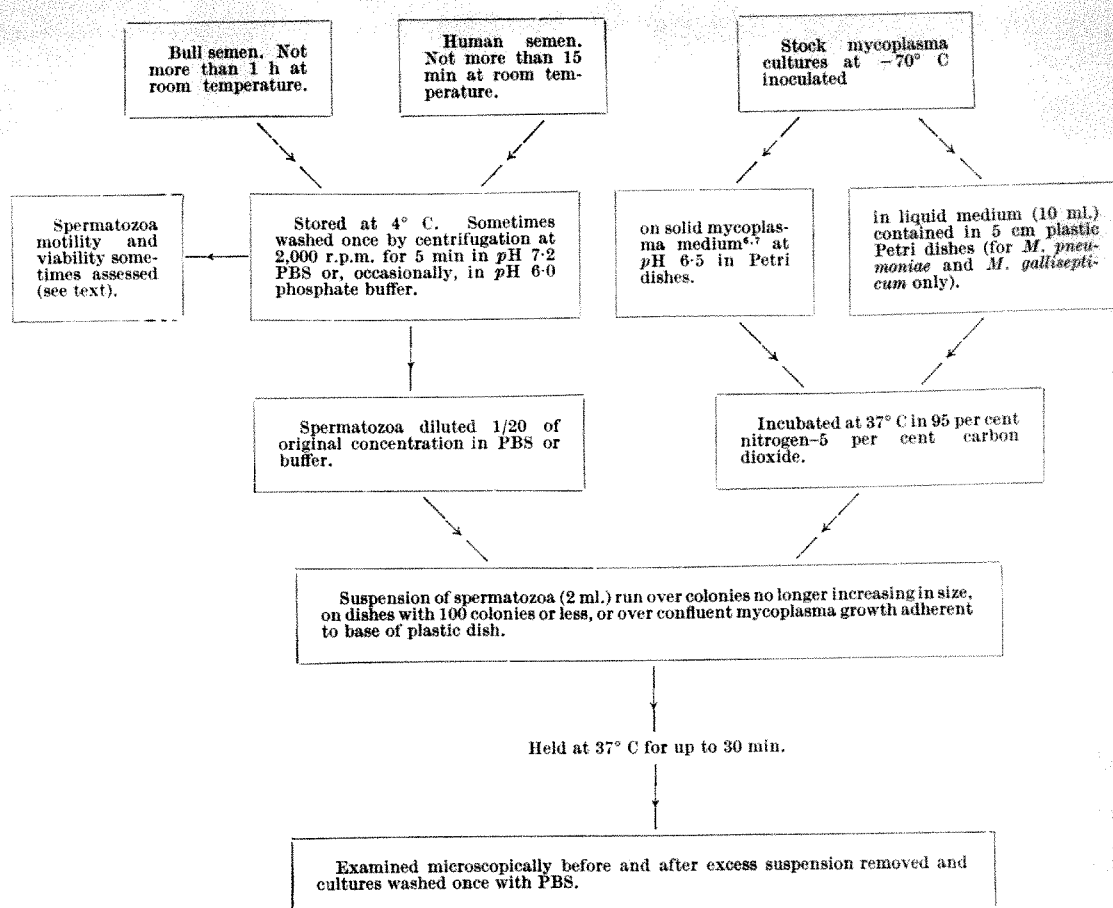

Fig. 1.

O erythrocytes to duplicate cultures. When ten colonies only were present, spermatozoa covered them completely; with increasing numbers of colonies, the extent to which the colony surfaces were covered with adherent spermatozoa diminished, so that no spermadsorption was observed with  $10^6$  colonies. A similar pattern was observed for haemadsorption. In further experiments, care was taken to use agar cultures on which there were no more than 100 colonies.

The effect of temperature on the speed of spermadsorption was then investigated. Dishes of agar medium, each with not more than 100 colonies of *M. pneumoniae* (FH strain), were incubated at 37° C, 22° C and 4° C with a suspension of bovine spermatozoa collected 4 h before. At various time intervals thereafter the extent of spermadsorption was recorded and the results are shown in Table 1. At 37° C adsorption was more rapid and colonies were more completely covered with spermatozoa than at 22° C. Thus adsorption after 50 min at 37° C was more extensive than after 5.5 h at 22° C. Furthermore, at 4° C spermadsorption was extremely poor, for colonies observed after 5.5 h had only one or two spermatozoa adherent to some of them; spermadsorption occurred, however, when the temperature of culture was changed to 37° C. In a similar experiment with colonies of *M. gallisepticum* (S6 strain), and human spermatozoa used within 30 min of collection,

spermadsorption occurred most rapidly and extensively at 37° C, although in this case extensive spermadsorption occurred also at 4° C after 2.5 h. In all further experiments colonies of mycoplasma and spermatozoa were incubated at 37° C.

The relationship between motility and viability of spermatozoa and their adsorption to colonies was investigated. Human semen was diluted twenty-fold in PBS, pH 7.2, and samples were held at 56° C, 36° C and 4° C. At various times the proportions of motile and viable spermatozoa in the suspensions were estimated and adsorption to colonies of *M. pneumoniae* (FH) and *M. gallisepticum* (S6) were observed after incubation at 37° C for 30 min. The results are given in Table 2. Twenty minutes after collection 90 per cent of the spermatozoa were actively motile and viable and spermadsorption was rapid and complete. Spermatozoa in suspensions incubated at 37° C for 9.5 h or at 56° C for 5 min were non-motile, but about half the spermatozoa remained viable and spermadsorption occurred, although less rapidly and less extensively than with an untreated spermatozoa suspension. Spermatozoa in suspensions subjected to a temperature of 56° C for 5.5 h were non-viable and adsorbed poorly. Subsequent experiments were successfully performed with semen which had been kept at 4° C after arrival at the laboratory and then used within 6 h.

Bovine spermatozoa after storage in liquid nitrogen also adsorbed, and the rate of attachment was only a little slower than that observed with a suspension of unstored spermatozoa and could be accounted for by the greater proportion of non-viable spermatozoa in the suspension that had been frozen (20 per cent compared with 10 per cent in the unfrozen suspension).

Adsorption could be demonstrated best with fresh spermatozoa at 37° C, and so further experiments were performed to determine how rapidly the phenomenon

Table 1. EFFECT OF TIME AND TEMPERATURE ON THE ADSORPTION OF BOVINE SPERMATOZOA TO COLONIES OF *M. pneumoniae*

Time after addition of spermatozoa	Spermadsorption at temperature indicated		
	37° C	22° C	4° C

5.5 h	++	+	±

±, 1 or 2 spermatozoa attached to edge of colony; ±, 5-25 per cent of colony surface covered by spermatozoa; +, 25-50 per cent; ++, 50-75 per cent.

Fig. 2. Adsorption of spermatozoa to colonies of the FH strain of *M. pneumoniae* ( $\times c. 175$ ). (A) Bovine spermatozoa after incubation at 37°C for 15 min. (B) Human spermatozoa after incubation at 37°C for 30 min.

occurred. Adsorption of human spermatozoa to colonies of *M. pneumoniae* and *M. gallisepticum* commenced as soon as the suspension, pre-warmed to 37°C, was added to the agar, also at 37°C. Likewise, guinea-pig erythrocytes adsorbed to colonies almost immediately.

Spermatozoa adsorbed strongly to mycoplasma colonies, even at 22°C and 4°C. Those which adsorbed to colonies of *M. pneumoniae* and *M. gallisepticum* at 37°C did not detach spontaneously even after 2 or 3 days at this temperature. It appeared that the spermatozoa merged with the colony surface as though autolysis had occurred, although this has not been examined in detail. It was sometimes possible, by repeated agitation of the agar culture, to detach the tails of spermatozoa while leaving the heads firmly attached to the colonies. Complete removal of spermatozoa could be achieved by extremely vigorous washing, that is by forcibly pipetting 10 ml. of

‡ One or two spermatozoa attached to edge of colonies.

PBS directly at a colony. This procedure, however, sometimes removed the surface of the colony from the agar before detaching the spermatozoa. If detachment was successful, spermadsorption occurred again when more spermatozoa were added.

Colonies of several haemadsorbing and non-haemadsorbing mycoplasmas were examined for spermadsorption. The results are shown in Table 3. Five mycoplasmas which exhibited haemadsorption were examined. Both human and bovine spermatozoa adsorbed to colonies of *M. pneumoniae* and *M. gallisepticum* (Fig. 3), as described previously, and also to colonies of *M. pulmonis*; only bovine spermatozoa adsorbed to colonies of *M. bovis genitalium*, while neither human nor bovine spermatozoa adsorbed to colonies of *M. agalactiae*. Colonies of *M. fermentans* and *M. hominis* type 1, mycoplasmas found in the human genital tract, neither spermadsorbed nor haemadsorbed.

In addition to adsorption of spermatozoa to colonies on agar medium, the adsorption of human spermatozoa to sheets of confluent growth of *M. pneumoniae* (FH) and *M. gallisepticum* (A514) adherent to plastic Petri dishes was demonstrated. Haemadsorption was shown also. Adsorption in these circumstances was surprising, for crowding of colonies on agar medium inhibited adsorption.

Table 3. SPERMADSORPTION AND HAEMADSORPTION WITH MYCOPLASMAS BELONGING TO DIFFERENT SEROTYPES

+, Adsorption demonstrated.

\* Adsorption with erythrocytes from man, fowl, mouse, cattle, goat and guinea-pig demonstrated with each mycoplasma.

Haemadsorption can be inhibited by specific antiserum, and therefore inhibition of adsorption of human spermatozoa to *M. pneumoniae* colonies was attempted with goat antiserum. Two-fold antiserum dilutions in 20 per cent unheated guinea-pig serum were added to the colonies, and these were kept at room temperature for 30 min. Then a suspension of spermatozoa was added and the colonies were incubated at 37°C for 1 h. Pre-inoculation goat serum at a dilution of 1:5 did not inhibit spermadsorption, but a 1:40 dilution of antiserum completely inhibited spermadsorption. The same antiserum inhibited haemadsorption also at a dilution of 1:40 and inhibited the colour change in a metabolic-inhibition test<sup>8</sup> at a dilution of 1:320. Neither haemadsorption nor spermadsorption was inhibited in the absence of unheated guinea-pig serum.

It was difficult to demonstrate spermagglutination with bovine spermatozoa even when washed spermatozoa were used. Several successful experiments were, however, performed with both washed and unwashed human spermatozoa and *M. gallisepticum* (A514) antigens. Human semen diluted twenty-fold in PBS produced an approximate 1 per cent suspension of spermatozoa. Erythrocytes were used at the same concentration. An equal volume of the antigen dilution was mixed with an equal volume of spermatozoa or erythrocyte suspension, the mixture agitated and then incubated at 37°C until the spermatozoa or erythrocytes had settled. Agglutinated spermatozoa produced a sheet covering the well, whereas unagglutinated spermatozoa formed a tight "button", similar to that observed with erythrocytes. This pattern was observed with both motile and non-motile spermatozoa and spermagglutination titres were similar with motile and non-motile spermatozoa. Spermagglutination titres were the same or only twice as small as haemagglutination titres obtained with either chicken or human erythrocytes. The results of comparative spermagglutina-

Fig. 3. Adsorption of human spermatozoa to a colony of the A514 strain of *M. gallisepticum*. (A) A colony before addition of spermatozoa. (B) A colony after incubation at 37° C for 10 min with spermatozoa ( $\times$  c.175).

tion and haemagglutination tests with *M. gallisepticum* are shown in Fig. 4.

In tests with 4–8  $\mu$  of antigen, an *M. gallisepticum* rabbit antiserum inhibited spermagglutination at an initial dilution of 1 : 16 and inhibited haemagglutination at a dilution of 1 : 64. Pre-immune rabbit serum did not inhibit at a dilution of 1 : 2.

Spermadsorption and haemadsorption by mycoplasmas have several common features which are summarized in Table 4. Adsorption of both spermatozoa and erythrocytes to colonies of *M. pneumoniae* may be inhibited by high concentrations of specific antiserum. The occurrence of inhibitors in bovine semen plasma<sup>1,2</sup> has not been a problem in spermadsorption experiments with the semen from the one bull used in the present investigation. On one occasion, however, spermatozoa from this bull adsorbed more rapidly after washing, suggesting the

Inhibited by antiserum	+	+

occurrence and possible fluctuation in concentration of an inhibitor in various ejaculates from one animal. This and the possible occurrence of inhibitors in samples of semen from other bulls need further investigation. Spermadsorption may be inhibited also by the crowding of colonies on agar medium. This is in contrast to the adsorption which occurs to confluent growth of mycoplasmas on plastic. The reason for this anomaly is not understood. It is possible, however, that some unknown factors are required at the colony surface for spermadsorption to occur and that these are readily supplied to growth on plastic by the overlying liquid medium and less easily to colonies on the surface of agar medium where many colonies could exhaust the required factors.

Spermadsorption experiments have been performed chiefly on those mycoplasma colonies which haemadsorb, and spermadsorption has usually been found to occur also. With *M. agalactiae*, however, haemadsorption but not spermadsorption was observed. It will be necessary to examine many more mycoplasma serotypes, particularly those that do not haemadsorb, before it is possible to determine how good a correlation exists between spermadsorption and haemadsorption. In addition, it is known<sup>5</sup> that not all strains within a given mycoplasma serotype haemadsorb, so it will also be necessary to examine several strains of a serotype.

The possible role of sialic acid in spermadsorption and haemadsorption should be kept in mind when considering the mechanism of these phenomena. It has been indicated that in the haemagglutination reaction, a sialic acid at the surface of turkey erythrocytes provides binding sites or receptors for *M. gallisepticum*<sup>9</sup>, although in other experiments removal of receptors on chicken erythrocytes by neuraminidase was not achieved<sup>10</sup>. If such a receptor mechanism is involved in spermadsorption it is difficult to understand why loss of spermatozoal viability should result in less rapid and quantitatively less spermatozoa adherence, unless loss of receptors on such spermatozoa also occurs. Some adsorption occurs when a suspension containing a complete population of non-viable spermatozoa is used. It is possible that in these circumstances the adhesion is similar to that observed when mycoplasmas adsorb on to inert substances such as polystyrene latex particles<sup>11</sup> or glass<sup>12</sup>.

We cannot yet assess the significance of our observations. Whether they have any relevance to the aetiology of infertility and foetal abnormalities and to the mechanism of transfer of infection within the female genital tract remains to be seen.

We thank Mr P. Dawson of the Hampshire Cattle Breeders Society Ltd., Lyndhurst, for supplying us with bovine semen and Mr M. R. Young and Mr F. Wanless of the Biophysics Department of the National Institute for Medical Research, Mill Hill, London, for the photography.

# Antigenicity in Mice of Antilymphocyte Gamma Globulin

by  
E. M. LANCE  
D. W. DRESSER

National Institute for Medical Research,  
Mill Hill, London, N.W.7

Antigenicity of  $\gamma$ G serum protein from rabbits immunized with mouse lymphocytes has been compared with that of  $\gamma$ G from normal rabbit serum. Results indicate that this property is not involved in the prolongation of homograft survival by antilymphocyte serum.

ANTISERA raised in rabbits against mouse lymphocytes exhibit potent immunosuppressive qualities. Investigation of rabbit serum fractions has shown that the component responsible for prolongation of skin homografts can only be demonstrated in the  $\gamma$ G fraction<sup>1,2</sup>. It is not known how antilymphocyte serum  $\gamma$ G exerts its effect. One possible mechanism is that of antigen competition, and so we have studied the antigenicity of antilymphocyte serum  $\gamma$ G by means of the antigen-elimination test.

In the experiments described here antilymphocyte serum was prepared in rabbits by immunizing them with the thymocytes of *CBA* mice, according to the procedure of Levey and Medawar<sup>3</sup>. We have investigated the response of *CBA* mice to gamma G globulin from both antilymphocyte serum and normal rabbit serum.

We used male mice, 10–20 weeks old. Gamma G globulin fractions were prepared from normal rabbit serum, and rabbit antilymphocyte serum by gel-filtration using 'Sephadex G-150' with a 0.2 molar phosphate saline buffer containing 0.002 molar ethyldiaminetetraacetic acid. The '7S' fraction was concentrated by pressure dialysis against 0.15 molar buffered saline and the concentration of protein was measured spectrophotometrically. Rabbit gamma globulin, fraction II by ethanol fractionation, was purchased from Pentex. The antigen-elimination assay was carried out by a standard method<sup>4</sup> using gamma globulins labelled with iodine-131 (ref. 5). The different immune responses of *CBA* mice to rabbit gamma globulin as defined by the rate of elimination of the labelled gamma globulin have been divided into categories 0–10. Each successive category (2–8) represents a two-fold increase in rate of antibody release into the circulation. Category 0 represents an undetectable antibody response and category 10 the maximum response. The categories were calibrated by passive immunization of mice injected with 2 mg of labelled rabbit gamma globulin; for the same absolute response the observed category is inversely related to the amount of test antigen used<sup>4</sup>. Fig. 1 illustrates these categories and this family of curves can be used as a "slide-rule" to quantify the experimental response. Protein solutions were centrifuged at 4,500*g* for 60 min before being injected intraperitoneally for both the antigen-elimination assay and the induction of immunological paralysis. The mice were immunized against rabbit gamma globulins by intraperitoneal injections of 0.1 mg of alum-precipitated gamma globulin<sup>6</sup> mixed with  $2 \times 10^8$  *Bordetella pertussis* organisms (RAP)<sup>4</sup>.

The experiments and results are summarized in Table 1. A single injection of 500  $\mu$ g of normal rabbit serum  $\gamma$ G (group A) is non-immunogenic and is eliminated from the circulation of previously untreated mice with a half-life of 5.4 days (Fig. 2). Using the categories given in Fig. 1 the geometric mean category was 0.2. In contradistinction, the same amount of antilymphocyte serum  $\gamma$ G is immunogenic (group B; geometric mean category 5.2, and Fig. 3). In groups C and D both normal rabbit serum  $\gamma$ G and antilymphocyte serum  $\gamma$ G are rapidly

Fig. 1. Categories of antigen-elimination responses. Based on passive immunization of *CBA* mice injected intraperitoneally on day 0 with 2 mg of labelled rabbit gamma globulin. In the range 2–8 the categories accurately reflect two-fold dilutions in the amount of passive antibody injected intraperitoneally immediately after test bleedings on days 2, 4, 6, 8 and 10 after injection of labelled antigen. Category 4 represents the injection every 2 days of sufficient antiserum to precipitate half ( $P_{50}$  per cent) of 28  $\mu$ g of labelled rabbit gamma globulin *in vitro*; category 5 is therefore the elimination response after passive immunization with twice this amount. The ordinate represents the percentage of the 2 mg of labelled rabbit gamma globulin left in the circulation.

Table 1

L	6	—	—	ALS (0.25–0.5 ml./week) for 14 weeks*	14	NRS $\gamma$ (500 $\mu$ g) + ALS 1 ml.*	1.1

NRS, normal rabbit serum; ALS, antilymphocyte serum; RGG, rabbit gamma globulin.

\*All injections were intraperitoneal, except for antilymphocyte serum, which was administered subcutaneously.

cleared in previously immunized animals. Comparison of groups *E* and *F* shows that mice injected with 200  $\mu$ g of normal rabbit serum  $\gamma$ G are at least eight times less responsive than mice injected with the same amount of antilymphocyte serum  $\gamma$ G (Figs. 4 and 5). Comparison of groups *C* and *E* shows that this suppressed response is the result of the induction of a degree of immunological paralysis. It is clear from Fig. 4 that mice receiving 200  $\mu$ g of normal rabbit serum  $\gamma$ G fall naturally into two groups, one of which shows a high degree of paralysis; this detail is lost in the geometric mean category of 6.7 (Table

1). Groups *G* and *H* demonstrate that paralysis induced by previous injection of 500  $\mu$ g of normal rabbit serum  $\gamma$ G also extends to a subsequent exposure to the other  $\gamma$ G.

In groups *I* and *J* (Table 1) the response to normal rabbit serum  $\gamma$ G was measured in mice previously exposed to "therapeutic doses" of antilymphocyte serum. These mice had received a total of 1 ml. of whole antilymphocyte serum subcutaneously, shortly after skin homografting. Survival of the skin homografts (*A*→*CBA*) was two to three times longer than on untreated mice. Twelve weeks later half the animals (group *I*) were challenged with

Fig. 2. Individual elimination curves in seven mice injected intraperitoneally with labelled normal rabbit serum  $\gamma$ G (group *A*). The half-life is 5.4 days.

Fig. 3. Similar to Fig. 2 but with labelled antilymphocyte serum  $\gamma$ G (group *B*). This figure shows a primary immune response.

Fig. 4. The elimination response in seven mice immunologically paralysed by 200  $\mu$ g normal rabbit serum  $\gamma$ G 2 weeks before challenge intraperitoneally with 100  $\mu$ g of alum-precipitated rabbit gamma globulin plus  $2 \times 10^6$  pertussis (RAP) followed by test 4 weeks later. Four of the mice show a considerable degree of paralysis (group *E*).

Fig. 5. Similar to Fig. 4, but the first injection was with 200  $\mu$ g of antilymphocyte serum  $\gamma$ G. It can be seen that all mice showed a considerable degree of immunity (group *F*).

RAP and subsequently both groups were tested with labelled normal rabbit serum  $\gamma$ G. Both groups eliminated the test antigen extremely rapidly, indicating that antilymphocyte serum is very immunogenic in doses producing potent immunosuppression. Group K shows that the inclusion of 1 ml. of antilymphocyte serum in the test dose of normal rabbit serum  $\gamma$ G injected into previously immunized mice induces only a minor suppression or delay of the immune response, which could be the result of what is in effect a large increase in the dose of test antigen<sup>4</sup>.

The administration for prolonged periods of time of weekly doses of antilymphocyte serum induces a state of unresponsiveness to normal rabbit serum  $\gamma$ G (group L). Although this state could be ascribed to non-specific immunosuppressive features of antilymphocyte serum, it is thought that a more likely explanation is that immunological paralysis has been induced by the large amount of  $\gamma$ G antigen present<sup>7</sup>.

These results show that normal rabbit serum  $\gamma$ G is a poor immunogen and readily induces a state of immunological paralysis, whereas antilymphocyte serum  $\gamma$ G is very immunogenic. On the other hand, a state of non-reactivity to antilymphocyte serum  $\gamma$ G can be induced either by previous paralysis with normal rabbit serum  $\gamma$ G or by chronic administration of closely spaced doses of antilymphocyte serum. The immunogenicity of this  $\gamma$ G may be explained in one of two ways. (a) It could act as a non-specific adjuvant stimulating immunization by the "normal" gamma globulins in the antilymphocyte serum preparation, or (b) the adherence of the molecules of antilymphocyte serum  $\gamma$ G to either macrophages or lymphocytes could be the decisive factor stimulating immunity as opposed to the paralysis induced by normal (non-adherent)  $\gamma$ G. The first possibility seems unlikely, for the antilymphocyte serum used in these experiments

usually caused immunosuppression in doses which still induced immunity to normal rabbit serum  $\gamma$ G. On the other hand, there is no question that antilymphocyte serum coats lymphocytes *in vivo*<sup>3</sup>, and one of us (E. M. L.) in unpublished preliminary experiments has tentatively shown that such coated cells are filtered from the circulation by the spleen.

Adler<sup>8</sup> has reviewed the evidence which shows that antigen competition may operate to produce decreased immunological responsiveness. Our results demonstrate that antilymphocyte serum is immunogenic, and so such a hypothesis must be considered. If antilymphocyte serum were to work by preoccupying the attention of all immunologically competent cells as obligative immunogen, then in conditions which prohibit immunity antilymphocyte serum should be ineffective. It has been found that the previous induction of paralysis using normal rabbit serum  $\gamma$ G did not diminish the potency of a subsequent "therapeutic" dose of antilymphocyte serum in prolonging skin homograft survival<sup>1</sup>. It therefore seems that the immunogenicity of antilymphocyte serum is irrelevant to its mode of action in the promotion of homograft survival.

This work was supported by grants from the National Institute of Arthritis and Metabolic Diseases, US National Institutes of Health.

## A GTP Requirement for Binding Initiator tRNA to Ribosomes

by

Hills Road, Cambridge

Formylmethionyl-tRNA (F-Met-tRNA<sub>F</sub>) is bound by particular codons to ribosomes in the initiation of protein synthesis. When a certain small concentration of magnesium ions is present, initiation factors and GTP are also required for this binding to take place. An analogue can be substituted for GTP, which suggests that this role of the nucleotide is uncoupled from its later hydrolysis.

FORMYLMETHIONYL-tRNA (F-Met-tRNA<sub>F</sub>)<sup>1,2</sup> has been demonstrated to be the initiator of protein synthesis in bacterial cell-free systems<sup>3-6</sup>. Of the two species of methionine-accepting tRNA present in *Escherichia coli* only the formylatable species, whether formylated or not, contributes methionine residues to N-terminal positions of polypeptide products<sup>3</sup>. Whereas both species of Met-tRNA respond to the codon AUG, F-Met-tRNA<sub>F</sub> also responds to GUG (refs. 3 and 7) and further differs from Met-tRNA<sub>M</sub> in that the formylatable species can directly enter the peptidyl-tRNA binding site of the ribosome<sup>8</sup>.

Two protein factors, F<sub>1</sub> and F<sub>2</sub>, which stimulate the translation of natural messenger RNA by washed ribosomes and supernatant enzymes have been isolated either from ribosomal washings<sup>9,10</sup> or from a DNA complex<sup>11</sup>. These factors are thought to be involved in the initiation step of protein synthesis, for F<sub>1</sub> and F<sub>2</sub> stimulate the bind-

ing of F-Met-tRNA<sub>F</sub> to ribosomes in the presence of AUG (ref. 12).

Since the initial demonstration of the requirement for GTP in protein synthesis<sup>13</sup>, a stoichiometric relationship has been found between the amount of GTP hydrolysed to GDP and *ortho*-phosphate on the one hand and the number of peptide bonds formed on the other<sup>14</sup>. The  $\beta$ , $\gamma$ -methylene analogue of GTP, 5'-guanylyl diphosphonate (GMP-PCP), has been shown to be a competitive inhibitor of the action of GTP in protein synthesis<sup>15</sup>. GTP has been reported to be needed in the formation of F-Met-puromycin from bound F-Met-tRNA<sub>F</sub> and puromycin<sup>16</sup>, and also for the formation of formylmethionyl-phenylalanine in a system directed by the synthetic messenger AUGUUU (ref. 17). These authors<sup>16,17</sup> concluded that GTP does not have its effect at the level of binding the F-Met-tRNA<sub>F</sub>, but in some way activates

Fig. 1. Each reaction mixture (50  $\mu$ l.) contained 0.10 molar *tris* acetate, pH 7.2, 0.05 molar potassium chloride, 0.01 molar ammonium chloride, 0.005 molar magnesium acetate, 0.94  $A_{260}$  units of ribosomes, 0.096  $A_{260}$  units of AUG, and 0.18  $A_{260}$  units of  $^{35}$ S-F-Met-tRNA ( $1.0 \times 10^6$  c.p.m. counted at 70 per cent efficiency in a Packard liquid scintillation spectrometer; 70 per cent as F-Met). Crude initiation factors (10  $\mu$ g/ $\mu$ l.) were added in the amounts indicated. When present, GTP was 0.0002 molar. After incubation at 25°C for 10 min, the reaction mixtures were diluted sixty-fold in 0.10 molar *tris* acetate, pH 7.2, 0.05 molar potassium chloride, 0.005 molar magnesium acetate (buffer B) and filtered on 'Millipore' filters by the procedure of Nirenberg and Leder<sup>21</sup>.

●, Plus factors and GTP; ▲, plus factors only.

it once bound. GTP stimulates the binding of *N*-acetylphenylalanyl-tRNA to ribosomes in the presence of polyuridylylate and initiation factors<sup>18</sup>. The stimulation of *N*-acetylphenylalanyl-tRNA binding by GTP occurred in the presence of a small concentration of magnesium.

We report here that GTP and initiation factors are required for the binding of F-Met-tRNA<sub>F</sub> to ribosomes with AUG at a 5 mmolar concentration of magnesium ions, and that in these conditions GMP-PCP is an effective substitute for GTP. Non-formylated Met-tRNA<sub>F</sub> does not bind in identical conditions. The stimulation of F-Met-tRNA<sub>F</sub> binding to ribosomes by either GMP-PCP or GTP indicates that the initial effect of GTP in protein synthesis has been uncoupled from a subsequent step in which hydrolysis of GTP occurs.

Ribosomes were prepared from cells of *E. coli* MRE600, after grinding with alumina. The broken-cell paste, suspended in 0.01 molar *tris* chloride, pH 7.4, 0.01 molar magnesium chloride, 0.06 molar ammonium chloride and 0.006 molar  $\beta$ -mercaptoethanol (buffer A), was freed of DNA by digestion with 3  $\mu$ g/ml. of DNase. After the removal of alumina and cellular debris from the cell extract by centrifugation at 30,000*g*, the ribosomes were pelleted at 230,000*g*, resuspended in buffer A and repelleted. Initiation factors were removed from the ribosomes by washing in a salt solution containing 0.01 molar *tris* chloride, pH 7.4, 0.01 molar magnesium chloride, 2.0 molar ammonium chloride, and 0.006 molar  $\beta$ -mercaptoethanol. The ribosomes were sedimented at 270,000*g* and the supernatant was retained for the initiation factors. The ribosomes were suspended in buffer A and sedimented again at 270,000*g*. After resuspension in buffer A, the ribosomes were stored in liquid nitrogen. The initiation factors were recovered from the high-salt ribosomal supernatant by ammonium sulphate precipitation (52 g/100 ml.). The precipitate was dissolved in a solution containing 0.02 molar *tris* chloride, pH 7.8, 0.002 molar magnesium acetate and 0.18 molar ammonium chloride, dialysed against the same buffer and stored in liquid nitrogen. F<sub>1</sub> and F<sub>2</sub> were fractionated by a procedure essentially the same as that described by Stanley and co-workers<sup>9</sup>.

tRNA from *E. coli* CA244 was charged with  $^{35}$ S-L-methionine (7,000 mc./mmole) and nineteen unlabelled

amino-acids in the presence of *N*<sub>10</sub>-formyl tetrahydrofolate with a crude *E. coli* supernatant fraction to prepare fully formylated  $^{35}$ S-F-Met-tRNA. To obtain non-formylated  $^{35}$ S-Met-tRNA, the formyl donor was omitted and the enzyme used was an *E. coli* supernatant fraction freed of the transformylase by passage through a phosphocellulose column. After treatment with phenol and two precipitations with ethanol, the charged tRNA preparations were passed through 'Sephadex G-25'. The extent of formylation was determined by treatment of aliquots with pancreatic ribonuclease followed by paper electrophoresis at pH 3.5. Preparations charged in the presence of the formyl donor usually yielded 70 per cent of the charged radioactivity as formylmethionyladenosine. In the absence of formyl donor, less than 2 per cent of the charged radioactivity corresponded to formylmethionyladenosine.

Triribonucleoside diphosphates permit the binding of amino-acyl-tRNA to ribosomes at concentrations of magnesium of 10 mmolar and more, but only poorly at 5 mmolar. F-Met-tRNA<sub>F</sub> binds exceptionally well with either AUG or GUG at 10 mmolar<sup>3,7</sup>, but at 5 mmolar almost none is bound. In contrast, when the RNA from the f2 bacteriophage is used in place of AUG, the maximum binding of F-Met-tRNA occurs in the presence of 5 mmolar magnesium ions<sup>19</sup>. In this context there are reports that only natural initiation occurs at a small concentration of magnesium<sup>20</sup>. If ribosomes are supplemented with GTP and initiation factors, a significant amount of F-Met-tRNA can be bound with the triplet AUG at a concentration of magnesium ions of 5 mmolar. GTP, the initiation factors and formylated Met-tRNA are required for this binding.

Fig. 1 shows the quantity of initiation factors required to give maximum stimulation of F-Met-tRNA binding to ribosomes with AUG and GTP with 5 mmolar magnesium ions. When the GTP is omitted the initiation factors cause only relatively small effects at any of the concentrations tested. With the preparation of ribosomes and initiation factors used, maximum stimulation was obtained with 1  $\mu$ g of initiation factors for each  $\mu$ g of ribosomes.

The specificity of this system is shown in Fig. 2. In the complete system containing ribosomes, AUG, initiation factors, GTP and F-Met-tRNA with 5 mmolar magnesium ions, the fully formylated F-Met-tRNA is bound rapidly, and the plateau is reached after about 10 min at 25°C. Both F<sub>1</sub> and F<sub>2</sub> are required. When either GTP or initiation factors are omitted, no binding occurs. Although not shown in Fig. 2, if AUG is omitted but both initiation factors and GTP are present, a blank

Fig. 2. The complete reaction mixture (250  $\mu$ l.) contained 0.10 molar *tris* acetate, pH 7.2, 0.05 molar potassium chloride, 0.01 molar ammonium chloride, 0.005 molar magnesium acetate, 4.7  $A_{260}$  units of ribosomes, 0.50  $A_{260}$  units of AUG, 75  $\mu$ g of initiation factors, 0.0002 molar GTP and either 0.53  $A_{260}$  units of  $^{35}$ S-F-Met-tRNA ( $3.2 \times 10^6$  c.p.m.; 70 per cent as F-Met) or 0.46  $A_{260}$  units of  $^{35}$ S-Met-tRNA ( $3.1 \times 10^6$  c.p.m.; less than 2 per cent as F-Met). Incubation was at 25°C. At the intervals indicated 25  $\mu$ l. samples were withdrawn, diluted 100-fold in buffer B, and filtered immediately on a 'Millipore' filter.

value of similar size is obtained. When non-formylated Met-tRNA is substituted for F-Met-tRNA, very little binding occurs with any combination of initiation factors and GTP. The failure of Met-tRNA to bind to ribosomes with 5 mmolar magnesium ions was shown not to be caused by any damage to the Met-tRNA, for significant amounts could be bound in the presence of 10 mmolar magnesium ions with or without initiation factors and GTP. Similar results were obtained with purified fractions of F-Met-tRNA<sub>F</sub> and Met-tRNA<sub>F</sub>. Met-tRNA<sub>M</sub> was not bound to ribosomes with AUG in the presence of 5 mmolar magnesium ions even in the presence of initiation factors and GTP.

Table 1. INITIATION FACTOR-STIMULATED BINDING OF <sup>35</sup>S-F-Met-tRNA TO RIBOSOMES

Triplet	Conditions Initiation factors	c.p.m. bound in the presence of GTP	GMP-PCP
None	+	2,400	2,000
None	-	250	280
AUG	+	21,800	20,700
AUG	-	1,420	820
GUG	+	8,570	16,300
GUG	-	530	560

Reaction mixtures (50  $\mu$ l.) contained 0.10 molar *tris* acetate, pH 7.2, 0.05 molar potassium acetate, 0.01 molar ammonium chloride, 0.005 molar magnesium acetate, 1.1 A<sub>260</sub> units of ribosomes, 0.096 A<sub>260</sub> units of AUG or 0.091 A<sub>260</sub> units of GUG, 30  $\mu$ g of initiation factors when indicated, 0.21 mmolar GTP or 0.18 mmolar GMP-PCP, and 0.10 A<sub>260</sub> units of <sup>35</sup>S-F-Met-tRNA (0.58  $\times 10^5$  c.p.m.; 70 per cent as F-Met). After incubation for 20 min at 25° C, the reaction mixtures were diluted 100-fold in buffer B and filtered on a 'Millipore' filter.

The specificity of the binding of F-Met-tRNA for GTP was also examined. Fig. 3 shows that GMP-PCP, the  $\beta,\gamma$ -methylene analogue of GTP, can substitute for GTP although the rate of binding is less. The stimulation observed with GMP-PCP sometimes approached the level of that observed with an equivalent amount of GTP (see Table 1). ATP and ITP can substitute for GTP to a lesser extent. It is possible that the effect seen with ATP results from the generation of GTP from endogenous GDP or GMP. The results obtained when UTP, CTP or GDP were substituted for GTP were indistinguishable from the blank. The stimulation by GMP-PCP, ATP and ITP did not result from contamination of these nucleotides with GTP, because the GMP-PCP had been treated extensively with alkaline phosphatase and the ATP and ITP had been chromatographed on Whatman No. 3 MM paper in the solvent *n*-propanol-ammonia-water (55/10/35 v/v) which separates GTP from other ribonucleoside triphosphates.

Evidence from an investigation of the synthesis of polypeptides *in vitro* directed by poly (UG)<sub>n</sub> and poly (AUG)<sub>n</sub> confirmed that both AUG and GUG are codons for F-Met-tRNA<sub>F</sub> (ref. 7). When the triplets AUG and GUG were compared in the initiation factor- and GTP-dependent binding reaction with F-Met-tRNA, the results shown in Table 1 were obtained. Both AUG and GUG significantly stimulated binding to a degree greater than that observed in the absence of triplet. When GMP-PCP was substituted for GTP, the binding observed with GUG more nearly approached that observed with AUG. The reason for the greater binding of F-Met-tRNA with GUG in the presence of GMP-PCP relative to GTP is not clear. In all cases the initiation factors were required.

We conclude that for F-Met-tRNA to be bound to ribosomes by the codons AUG or GUG with 5 mmolar magnesium ions, the formyl group, initiation factors and GTP are all obligatorily required. The observation that an analogue of GTP (which cannot be degraded in the manner in which GTP is normally hydrolysed) can effectively substitute for GTP implies that this role of GTP has been uncoupled from the subsequent step in which it is hydrolysed.

Finally, we must emphasize that the effects observed here only describe the binding of F-Met-tRNA<sub>F</sub> with 5 mmolar magnesium ion. As the concentration of mag-

Fig. 3. Each reaction mixture (125  $\mu$ l.) contained 0.10 molar *tris* acetate, pH 7.2, 0.05 molar potassium chloride, 0.01 molar ammonium chloride, 0.005 molar magnesium acetate, 2.4 A<sub>260</sub> units of ribosomes, 0.31 A<sub>260</sub> units of AUG, 38  $\mu$ g of initiation factors and 0.90 A<sub>260</sub> units of <sup>35</sup>S-F-Met-tRNA which had been pyrophosphorylated to remove all amino-acids except the formylated-methionine ( $1.76 \times 10^5$  c.p.m.). As indicated below, GTP was 0.26 mmolar, GMP-PCP was 0.26 mmolar, ATP was 0.24 mmolar and ITP was 0.21 mmolar. Incubation was at 25° C. At the intervals indicated 25  $\mu$ l. samples were withdrawn, diluted forty-fold in buffer B and filtered on 'Millipore' filters. ●, GTP; ▲, GMP-PCP; ×, ATP; ■, ITP; ○, blank.

nesium ions is increased to 10 mmolar, the requirements for the formyl group, initiation factors and GTP become less accentuated, or disappear altogether. We believe that our previous conclusions<sup>3,8</sup> about the special structure of tRNA<sub>F</sub> and its relation to ribosomal binding sites at 10 mmolar magnesium ion are correct.

We thank Dr R. E. Monro for the GMP-PCP and Mr W. A. Whybrow for technical assistance. We also thank the Microbiological Research Establishment, Porton, Wiltshire, for supplying tRNA and frozen cells of *E. coli*. One of us (J. S. A.) is a US Public Health Service Postdoctoral Fellow.

## LETTERS TO THE EDITOR

## ASTRONOMY

## An Upper Limit to Circularly Polarized Radiation from the Crab Nebula

RECENTLY a small intense source of low frequency radio emission has been detected in the Crab Nebula<sup>1,2</sup>. Subsequent investigations have revealed that this source has a flux spectral index of  $\alpha \sim 1.2$  (refs. 2 and 3), an angular diameter of  $\sim 0.2$  sec arc (refs. 3 and 4), and a brightness temperature of  $\sim 10^{11}$  °K (ref. 4). Neither the thermal nor the synchrotron emission mechanisms can satisfactorily account for these characteristics<sup>3-5</sup>. Accordingly, a plasma mechanism, possibly similar to that of a solar flare, has been proposed<sup>4,5</sup>. It seems likely that such a mechanism would be associated with the stellar remnant of the supposed supernova which gave rise to the Crab Nebula, and a recent measurement of the position of the compact source indicates that it does indeed coincide with the position of the stellar remnant<sup>6</sup>.

Ginzburg and Ozernoy<sup>5</sup> stated that radiation from a plasma mechanism would probably be strongly circularly or elliptically polarized. The present communication reports a search for such polarized radiation from the Crab Nebula (Tau A) at a frequency of 40 Mc/s using the 1,000 ft. diameter radio telescope of the Arecibo Ionospheric Observatory. At this frequency the compact source accounts for  $\sim 20$  per cent of the integrated radiation from the nebula<sup>1,4</sup>.

The telescope has been described previously<sup>7</sup>. The reflector was illuminated by two orthogonal pairs of Yagi antennae. The signals from each pair were combined in a hybrid network in such a way that two output signals were obtained, corresponding to right and left circular polarization respectively. These outputs, shown as channels A and B in Fig. 1, were amplified and detected independently. Bandwidths of 25 kc/s and 125 kc/s were used simultaneously on each channel; if the radiation were elliptically rather than circularly polarized the percentage polarization would be less at the wider bandwidth because of Faraday rotation in the Nebula. The final outputs were recorded by both a magnetic tape unit, for computer processing, and a pen recorder.

The receiving system, which is illustrated schematically in Fig. 1, could be operated in two switching modes. There was a half-wave switch preceding one input of the hybrid, and a Dicke switch following the hybrid in each of channels A and B. In the first mode of operation, which was used to detect the circularly polarized component of the radiation, the half-wave switch was operated at 400 c/s and the Dicke switches held in the positions connecting the receivers to the antenna. After synchronous detection, the outputs from channels A and B corresponded to circularly polarized signals in the senses left minus right, and right minus left, respectively. The sense of the output was determined by transmitting a circularly polarized signal from a small antenna erected in the centre of the reflecting surface. In the second mode of operation, which was used to detect the total emission from the nebula in one polarization, the half-wave switch was held in position and the Dicke switch was operated, using a diode noise source as a reference load. The effective temperature of the reference load was maintained at a level approximately equal to the sky

brightness temperature in order to reduce effects arising from non-linearity in the receiving system. A second diode noise source connected to each channel through a directional coupler was used in this switching mode to monitor the gain stability of the receiving system. By using these two switching modes successively the circularly polarized component of the radiation could be expressed directly as a fraction of the total emission from the nebula.

The half-power beamwidth of the antenna at 40 Mc/s was  $2.0^\circ$ . Each source observed remained within the tracking range of the telescope for  $\sim 2$  h. An observation consisted of tracking the source for 5 min, and establishing a baseline by tracking, for three minutes each, the positions 15 min of R.A. earlier and later than the source. The sequence was off-source earlier, on source, then off-source later, so that the zenith angle was approximately constant throughout each observation. This method reduced to a minimum any spurious effects which arose from illuminating different portions of the fixed reflector surface. This method of observation was used for both switching modes. A receiver time constant of 0.1 sec was used during the observations to allow analysis of the circularly polarized component of the radiation for evidence of the interplanetary scintillations which would be expected for radiation from the compact source during the time of the observations (March 1967)<sup>3,4,8</sup>. Sample records showing observations of the Crab Nebula are reproduced in Fig. 2.

Before reduction of the observations, the non-linearity of the receivers was measured by periodically injecting a constant noise signal through the directional couplers during a drift scan observation of Virgo A. The dependence of the antenna gain on zenith angle was determined using observations of the Crab Nebula. Coupling between the orthogonal pairs of Yagi antennas was  $\sim -27$  dB. Measurements of the phase error of the system indicated that it was  $\sim 10^\circ$ , which has a negligible effect on the measured amplitude of the circularly

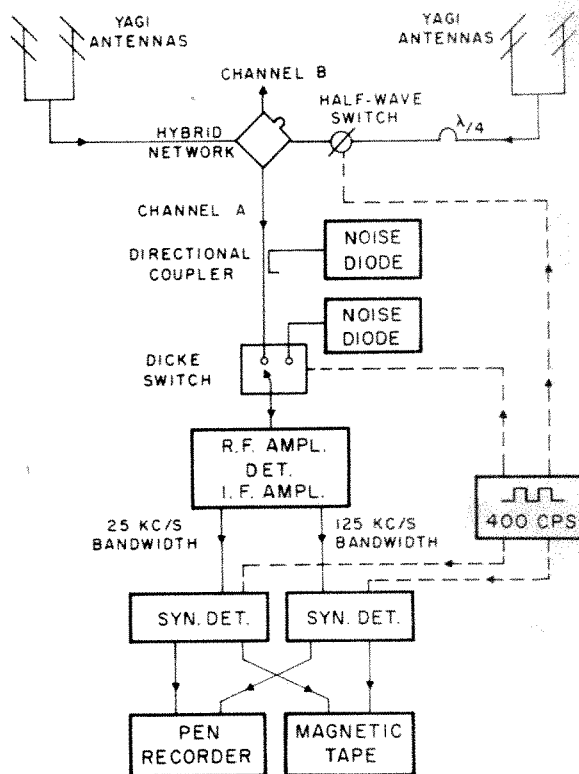

Fig. 1. The receiving system.

polarized signal. After correcting for non-linearity and zenith angle effects, the output representing the apparent circularly polarized signal was expressed as a fraction of the total emission for each channel and at each bandwidth independently. For each bandwidth the channel *B* values were subtracted from the channel *A* values; these channels represented opposite senses of the polarization. This procedure eliminated the systematic error arising from the difference in attenuation between the two positions of the half-wave switch.

Fig. 2. Sample records of Taurus *A* observations: (i) Dicke switching; (ii) half-wave switching. The four traces are (a) channel *A*, 125 kc/s; (b) channel *A*, 25 kc/s; (c) channel *B*, 25 kc/s; (d) channel *B*, 125 kc/s. The indicated sections of the records represent (a) off-source earlier; (b) on-source; (c) off-source later; (d) noise injection from diode noise source, one channel only.

Fig. 3. Apparent circular polarization at 40 Mc/s. *P* is defined as  $100 \times (\text{left circ.} - \text{right circ.}) / (\text{left circ.} + \text{right circ.})$ . The measurements with 125 kc/s bandwidth are represented by circles and those with 25 kc/s by crosses. The plotted points for each source are arranged in chronological order of observation.

Observations were made of the Crab Nebula and of three reference sources, Virgo *A*, 3C 123 and IC 443. There is no reason to expect a circularly polarized signal from any of the reference sources. Fig. 3 shows the polarized signal measured for each bandwidth during each independent observation of the four sources. It is clear that a small systematic effect was present, characteristic of absolute measurements. The circular polarization of the radiation from the Crab Nebula, however, was determined relative to that from the three reference sources, thus eliminating this systematic error. A weighted mean of the data illustrated in Fig. 3 was calculated for the three reference sources together and for the Crab Nebula. The difference between the two means, which expresses the circularly polarized signal from the Crab Nebula, gave a value of  $(0.4 \pm 0.5)$  per cent right circular polarization. There was no significant difference between the results obtained from the 25 kc/s bandwidth observations and those using the 125 kc/s bandwidth.

Assuming that the compact source contributes about 20 per cent of the total radiation from the Crab Nebula<sup>1,4</sup>, the above answer corresponds to  $(2.0 \pm 2.5)$  per cent right circular polarization of the compact source. The absence of significant circular polarization does not rule out a plasma mechanism, but indicates that if a plasma mechanism is responsible for the emission from the compact source, then the magnetic field in the source does not play an important part in the process.

We are indebted to Mr F. S. Harris for his generous and valuable assistance in this work. Two of us (B. H. A. and C. R. P.) thank Dr F. D. Drake for making available to us the many facilities of the Arecibo Ionospheric Observatory.

### Profile of the Unidentified Interstellar Absorption Band at 6180 Å at Different Galactic Longitudes

THERE is evidence<sup>1</sup> that the profile of the unidentified interstellar absorption band at 4430 Å is constant over a range of galactic longitudes. This band is the strongest of a number of apparently similar bands centred on wavelengths of 6180 Å, 4890 Å and 4760 Å. The band at 6180 Å was first noticed by Wilson<sup>2</sup>, who speculated as to an interstellar origin. The second band, at 4890 Å, was discovered independently by Wilson<sup>3</sup> and by Butler and Seddon<sup>4</sup>, while the third was tentatively identified as interstellar by Merrill in private correspondence with Beals<sup>5</sup>. The only evidence presented so far about the interstellar nature of these bands, apart from studies of correlation of strengths with those of known interstellar absorptions, comes from Merrill and Humason<sup>6</sup>, who have shown that the position of the 4430 Å band is stationary with respect to stellar absorption lines in the spectrum of an early type binary star. Strength correlation is difficult for all these bands because of their weakness and width, and has only been attempted for the band at 4430 Å. For the same reasons profile determination is difficult, but may well be crucial in the identification of their origin.

The band at 6180 Å is, apart from that at 4430 Å, the most suitable for such investigations because it is not appreciably affected by stellar or atmospheric line absorption. Measurements in this wavelength region made in the course of the spectrophotometric investigation of early-type stars carried out at this observatory<sup>7</sup> are available for the stars used in the determination of the 4430 Å profile<sup>1</sup>. Because the central depth of the feature at 6180 Å is only about one-third that of the 4430 Å band, it has not been thought worthwhile to reproduce the mean spectra in each of the three regions of galactic longitude used in this earlier work<sup>1</sup>, but simply to show the differences between them. The three groups are defined as: group 1 (Cygnus),  $020^\circ < l < 120^\circ$ ; group 2 (Perseus),  $120^\circ < l < 145^\circ$ ; and group 3 (Auriga-Gemini),

$145^\circ < l < 190^\circ$ ; and the stars used are those given in Table 1 of ref. 1. The ordinates in Fig. 1 are all on a magnitude scale; the abscissa is approximately linear in wave-number. The top two traces are of magnitude differences between group 1 and group 2 and between group 1 and group 3. It can be seen that almost all stellar and interstellar features are cancelled out. Those features that have not been cancelled out are (a) the general slow curvature over the whole of  $m_1 - m_2$ , (b) a peak in  $m_1 - m_2$  at about 6285 Å, and (c) an apparent absorption line at 6401 Å in region 1 which is missing in regions 2 and 3. Effect (a) almost certainly arises from the use of two different photographic emulsions at different times in the original programme of measurements. Group 2 contains more measures from Kodak '103a-F' emulsions than the average, and groups 1 and 3 more from Ilford 'Astra VIII'. Curvature of the wavelength/sensitivity characteristics is much more pronounced in the red and yellow than in the blue, and is more difficult to balance out. This curvature will not significantly affect the measures, except as to be noted later. Effect (b) corresponds to a greater absorption in region 2 than in region 1 at about 6285 Å. It does not appear to be related to the interstellar absorption at 6284 Å, because its centre is well separated, and for the same reason it does not appear to arise from greater atmospheric absorption by the  $\alpha$ -band of oxygen. It does appear, however, to be real, as also does the absorption at 6401 Å in group 1. No explanation is offered for either of these two lines, except to acknowledge that the feature (b) may result from a difference between the profiles of the interstellar line 6284 in Cygnus and Perseus. This difference, if it exists, is not present in the comparison of Cygnus with Auriga-Gemini.

It can be seen that the interstellar features at 6284 Å, 6203 Å and 6180 Å have been cancelled out, which indicates that the profiles and strengths of these features are intercorrelated, as they are<sup>1</sup> with the band at 4430 Å and the colour excess, because the same groupings of the same stars have been used throughout. This leads one to suspect that the causes of the continuous interstellar absorption

Fig. 1.

and of the diffuse lines are closely linked in the same way as has already been suggested for the diffuse bands and that they are different effects of the same cause.

Because 6180 Å has the same profile in each group, the three profiles have been averaged to increase the signal to noise ratio, as was done for 4430 Å. This mean trace is the third in Fig. 1 and is labelled "sum". The standard error per point is  $\pm 0.003$  magnitude, the total number of plates used being 85. Because of the curvature mentioned earlier, a smooth curve has been inserted through regions expected to be free from absorption. As can be seen, the curvature is slight and errors in it will not greatly affect the profile of 6180 Å.

The fourth trace is the sum trace rectified to the inserted curve. The smooth profile inserted in the 6180 Å band has not been fitted to the tracing but is the profile of 4430 Å derived in ref. 1, scaled down for the different central depth, and extended in the wavelength direction by the ratio 6180:4430. The fit is surprisingly good. There is a real deviation from this profile centred on 6203 Å. This feature is interstellar in origin<sup>8</sup>. Its position, profile and amplitude relative to 6180 Å appear to be constant and so it can be thought of as part of the composite 6180 Å profile, in which case the 6180 Å profile would not resemble that of the 4430 Å band. Wilson<sup>3</sup>, however, has pointed out that no other diffuse line is associated with a band, even if much more intense than 6203 Å. Probably they should be considered to be separate. With this in mind, the inserted profile has been subtracted from the composite around 6203 Å, giving the short trace below, labelled "Derived Profile 6203 Å Interstellar". Too much significance should not be attached to this profile. It may be noted that the profile has the same half-width as the adjacent strong interstellar line at 6284 Å.

The inserted profile derived from 4430 Å seems a good fit for 6180 Å. Its centre is, however, at 6175 Å, the wavelength of 6180 Å having been attributed on much less satisfactory profiles. The equivalent width of the whole feature 6180 + 6203 is 1.30 Angstrom units, of which 6180 is responsible for 1.03 Å. The equivalent width of the 4430 Å band derived in ref. 1 is 2.18 Å. It would seem that the relative strength of 4430 Å to 6180 Å is in the ratio 2:1, within the errors involved here. The width of 6180 Å at half the central depression is 29 Å, as compared with 21 Å for 4430 Å. It was noted in the earlier communication that 4430 Å profiles in the three regions of galactic longitude fortuitously cancelled out in strength as well as width. We see here that the same cancellation has taken place, that is to say, that the aforementioned ratio of strengths of 4430 to 6180 of 2:1 appears to be constant in these longitude regions at least, and may indicate that the two bands arise from the same process, and are to be expected always to have the same ratio. It may also be that the diffuse lines 6284 Å and 6203 Å are also closely connected, because they also cancel out. It has already been noted that the cancellation of 4430 Å profiles is frequently to be found with equal reddening and equal colour excess. It is not possible to say here much about the strength of the intense diffuse line 6284 Å, because it is so heavily involved in the  $\alpha$ -band absorption of atmospheric oxygen, and is in any event not resolved here from the other weak interstellar diffuse line at 6270 Å. The total combined strength of 6284 Å and 6270 Å is, however, close to 1.4 equivalent Angstroms after allowance has been made for atmospheric absorption, from corrections derived in the original sources<sup>4,7,9</sup>. The ratio of the strengths of 6284 Å and 6203 Å is then about 5:1.

In the earlier communication<sup>1</sup> on 4430 Å, a double Gaussian profile was assumed and fitted. The same profile has been shown to fit 6180 Å well, with the further assumption that  $\Delta\lambda/\lambda$  is equal for any two equivalent points on the two profiles, where  $\Delta\lambda$  is the wavelength difference of a point from the centre of the profile  $\lambda_0$ .

The validity of these two assumptions could lead to a decision between mechanisms.

It is a pleasure to acknowledge the assistance of Professor Brück and Drs Ireland, Nandy, Reddish and Wolstencroft in the preparation of this report.

## PLANETARY SCIENCE

### Rare Earth Content of Green Fluorite— a New Source of Europium

A CONNEXION has already been noted between the rare earth content of fluorites, their colour and their fluorescence when viewed under ultra-violet light<sup>1</sup>. Europium has been indicated as probably responsible for the blue component of the observed fluorescence, and ytterbium for the green component.

From a series of approximate analyses of specimens from the North Pennine Orefield, it was reported that those fluorite samples exhibiting the greatest fluorescence were both rich in europium and poor in cerium. This combination favours the known solvent extraction procedures for europium. In view of this, and of the recent increased importance of europium, it has been considered desirable to re-examine the material from this orefield as a possible domestic source of europium compounds. Dr K. C. Dunham kindly provided some of the original sample material on which the earlier observations were based, and the content of europium has been re-determined.

The original determinations were made by a spectrographic method, but this was not considered to be sufficiently precise, and a neutron activation procedure was devised. This procedure involved irradiation in BEPO at a neutron flux of  $10^{12}$  n/cm<sup>2</sup>sec, precipitation of total rare earths as oxalates, a separation of europium by amalgam-exchange according to the method described by Malan and Münzel<sup>2</sup>, counting of europium-152 by  $\gamma$ -spectrometry, and finally a determination of the chemical yield by cathode ray polarography.

The results obtained are given in Table 1, where they are compared with the original results. It is clear from this work that samples of fluorite from this orefield do contain appreciable amounts of europium, although not all the specimens examined were as rich as had earlier been supposed. The specimen richest in europium was the only one to give a really intense fluorescence—the green material from Stotfield Burn Mine.

Table 1. A COMPARISON OF APPROXIMATE SPECTROGRAPHIC RESULTS WITH THOSE OBTAINED BY NEUTRON ACTIVATION ANALYSIS

Sample No.	Locality	Fluorescence under ultra-violet light	Europium (p.p.m.) Spectro- Neutron-graphic activation
63	Stotfield Burn Mine	Intense, bluish white	90 132
64	Stotfield Burn Mine	Moderate, purple	20 41
65	Stotfield Burn Mine	Weak, purple	15 7
1419	Boltsburn East Mine	Weak, bluish	50 24
1501	Rispey Mill, tailings	Weak, bluish	70 23
1502	Sharnberry, high level dumps	Weak, bluish	100 42
1503	California Mine dumps (non-uniform material)	Some grains strong, bluish; others moderate, purple	110 43
1505	Rotherhope Fell Mine	Moderate, purple	30 15

Table 2. APPROXIMATE SPECTROGRAPHIC ANALYSIS OF FLUORITE SAMPLES FROM REDBURN MINE, CO. DURHAM

Sample No.: Colour: Fluorescence:	67/1925 Green Intense, bluish	67/1926 Purple Strong, purple	67/1927 Colourless Weak, purple
Analysis (p.p.m.)			
Lanthanum	200	< 5	5
Cerium	< 5	5	5
Praseodymium	20	< 20	< 20
Neodymium	200	< 20	< 20
Samarium	20	< 20	< 20
Europium	80	5	8
Gadolinium	10	< 1	2
Terbium	< 20	< 20	< 20
Dysprosium	50	10	10
Holmium	10	< 10	< 10
Erbium	20	10	10
Thulium	< 10	< 10	< 10
Ytterbium	7	5	5
Lutetium	< 10	< 10	< 10
Yttrium	~ 500	~ 500	~ 500

At present the only mine in the area producing green fluorite in any quantity is Redburn Mine, working the Red Vein, north of Rookhope Village, which also produces purple and colourless varieties. An approximate spectrographic determination of individual rare earths in these three varieties (Table 2) has shown that, in this mine too, it is the green variety that is rich in europium. This variety also exhibits an intense bluish fluorescence similar to that observed from the green variety from Stotfield Burn Mine, which also works the Red Vein, but south of Rookhope Village.

The extent of variation of the europium content of green fluorite is not known, but analyses obtained so far have indicated that a general level of 100 p.p.m. can be expected in the material from the Red Vein. Any process designed exclusively to produce europium from this material is likely to prove economically unattractive. A process, designed to recover a rare-earth concentrate as a by-product from plants utilizing this fluorite for the production of fluorine chemicals, would give a material rich in europium and poor in cerium that would be a convenient starting material for the extraction of europium.

### Graptolites of the *Monograptus hercynicus* Type recorded from Malaya

I RECORDED Lower Silurian graptolites from Malaya 8 years ago<sup>1</sup>. Since their discovery during the geological mapping of the Langkawi Islands large areas of north-west and central Malaya have been systematically mapped on a 1 in. : 1 mile scale by the Geological Survey of West Malaysia. As a result of this work more than 100 further graptolite localities have been found in Kedah, Perak and Pahang States, and among the graptolites found have been those of *Monograptus hercynicus* type, which has previously been described only from Central Europe, the Yukon Territory and Australia. I am now examining collections of these fossils.

The majority of the graptolites are within the range Llandoveryan to Wenlockian, but it is very interesting that material from at least seven localities contains recognizable monograptids of the *M. hercynicus* type. Although these latter fossils are usually poorly preserved there is enough detail to permit comparison with the following described species: *Monograptus hemiodon* Jaeger, *Monograptus praehercynicus* Jaeger, *Monograptus uniformis* Pribyl and *Monograptus yukonensis* Jackson and Lenz. Two new species of the group are also present.

The descriptive palaeontology, stratigraphical significance and distribution of *M. hercynicus* type monograptids, which are among the youngest graptolites to occur, have only recently been made known by the work of Jaeger<sup>2,3</sup>. Although Perner<sup>4</sup> in 1899 described two species from beds in Bohemia which he considered might be of Devonian age, it remained for Jaeger to show conclusively that these graptolites were confined to beds of post-Ludlow age. The researches of Jaeger in Central Europe and of Jackson and Lenz<sup>5</sup> in the Yukon Territory of Canada, together with other instances from North America and Central Asia quoted by Berry<sup>6</sup>, indicate that shelly faunas which are either intimately or closely associated with these graptolites are of early Devonian aspect and more precisely they allow correlation of the host strata with the Gedinian and part of the Siegenian Stages.

In Malaya the suggested Lower Devonian chronology is corroborated by the frequent association of *M. hercynicus* type monograptids with daeryoconarid tentaculites. Several forms of these pelagic organisms can be distinguished. Bouček (personal communication) has identified the ribbed species *Tentaculites matlockianus* Chapman and the smooth shell *Styliolina fissurella* (Hall). *T. matlockianus* is said to be very close, if not identical, to *Novakia acuarina* Richter of middle Lower Devonian age and the styliolinid is indicative of a Lower to Middle Devonian age.

The intention of this preliminary communication is to put on record a further global occurrence of monograptids of the *M. hercynicus* group. It is also gratifying to note that these and the abundance of the earlier Silurian graptolites have assisted greatly in determining the lower and middle Palaeozoic age of strata covering more than 2,000 square miles of Malaya which were previously classed as Late Palaeozoic and Early Mesozoic.

## PHYSICS

### Atmospheric Electric Field as a Possible Cause of Radio Pulses from Extensive Air Showers

VARIOUS mechanisms have been proposed for the origin of the radio pulses which are found<sup>1-6</sup> to be associated with large cosmic-ray extensive air showers. While these proposed mechanisms differ in detail, they all depend essentially either on enhanced Cherenkov radiation from an electron excess in the shower<sup>7</sup> or on charge separation effects in the Earth's magnetic field<sup>8</sup>; these effects are believed to contribute about equally to the observed pulses<sup>2</sup>. It appears that charge separation by the electric field of the lower atmosphere may also play a significant part under certain atmospheric conditions.

The existence of a vertical electric potential gradient in the atmosphere has long been known; the surface of the Earth carries a negative charge and the upper layers of the air a positive one. At altitudes of up to a few kilometres the average fine-weather field is  $\sim 100$  V m<sup>-1</sup> and above this height the gradient falls steadily to a value  $\sim 1$  V m<sup>-1</sup> at an altitude of  $\sim 20$  km. The precise values vary with locality, time, season and weather. Under disturbed weather conditions the vertical gradient may be much higher. Gradients of  $\sim 500$  V m<sup>-1</sup> occur

near the ground in drizzle, while under thunderclouds the gradient may reach  $\sim 50,000 \text{ V m}^{-1}$  (see, for example, Schonland<sup>9</sup>). Reversals of the field direction with varying altitude also occur and the field may have considerable horizontal components<sup>10</sup>.

The particles of an extensive air shower will suffer a systematic transverse separation according to their charge under the influence of the component of the potential gradient which is perpendicular to the shower arrival direction. This results in the formation of a dipole and a transverse current which are exactly analogous to those caused by the magnetic separation effect discussed by Kahn and Lerche<sup>6</sup>. The transverse acceleration of a positive or negative electron moving at relativistic speed is  $eE_T/\gamma m_0$ , where  $e$  is the electron charge,  $\gamma m_0$  is the electron mass,  $m_0$  is the electron rest mass and  $E_T$  is the component of the field perpendicular to the shower motion. The resultant separation between a pair produced at one point is

$$\Delta_{TE} = \frac{eE_T}{\gamma m_0} \tau^2$$

where  $\tau$ , the particle lifetime, is  $\sim$  one radiation length/ $c$ , that is,  $\sim 10^{-6}$  sec near sea level;  $c$  is the velocity of light. This compares with a separation due to the Earth's magnetic field

$$\Delta_{TM} = \frac{eH_T c}{\gamma m_0} \tau^2$$

where  $H_T$  is the component of the Earth's magnetic field perpendicular to the shower motion. For the transverse separations due to the electric and magnetic fields to be comparable we find  $E_T \sim H_T c$  which with  $H_T \sim 0.2$  oersteds gives  $E_T \sim 6 \times 10^9 \text{ e.m.u./cm}$  or  $6 \times 10^3 \text{ V m}^{-1}$ . This is much higher than the normal fair weather field of the atmosphere but is frequently attained in thundery conditions when such fields may extend over many ( $\sim 10^3$ ) cubic kilometres of space. It appears then that under some atmospheric conditions the yield of radio emission from extensive air showers could be considerably enhanced by the transverse separation of charge caused by the atmospheric electric field.

We now consider the charge separation produced along the direction of shower motion by the component of the potential gradient,  $E_p$ , parallel to this direction; there is no magnetic analogy to this case. This separation

$$\Delta_{PE} = \frac{eE_p}{\gamma^3 m_0} \tau^2$$

Taking  $\gamma = 40$  (20 MeV electrons at the Cherenkov threshold for air),  $e/m_0 = 1.8 \times 10^{11} \text{ coulombs kg}^{-1}$  and  $E_p \sim 100 \text{ V m}^{-1}$  we find  $\Delta_{PE} \sim 3 \times 10^{-4} \text{ m}$ . Disregarding charge excess effects, the shower can now be approximated as an array of dipoles of this length, oriented with their axes parallel to the motion of the shower, the dipoles being distributed within the shower disk  $\sim 100 \text{ m}$  across and  $\sim 2 \text{ m}$  thick.

For wavelengths where  $\lambda \gg \Delta_{PE}$  we may write, following Jelley<sup>11</sup>, that the ratio of the yield of energy per unit bandwidth per unit time of dipole Cherenkov radiation,  $W_{PE}$ , to normal Cherenkov radiation,  $W_0$ , is given by

$$\frac{W_{PE}}{W_0} \sim \frac{p^2 \omega^2}{e^2 v^2} \sim \frac{\Delta_{PE}^2 \omega^2}{c^2} \sim \frac{4\pi^2 \Delta_{PE}^2}{\lambda^2}$$

where  $v$  is the particle velocity ( $\sim c$ ),  $\omega$  is the angular frequency of the radiation of wavelength  $\lambda$ , and  $p$  is the dipole moment.

Considering wavelengths where  $\lambda > 3 \text{ m}$ , all the dipoles will be radiating in phase for a suitably placed observer, because they are confined within a disk  $\sim 2 \text{ m}$  thick. The ratio of the dipole Cherenkov yield to the normal Cherenkov yield for the whole shower containing  $N$  particles is

therefore  $\frac{W_{PE}}{W_0} \sim \frac{N^2}{4} : N$ , that is, an enhancement of

$\sim \pi^2 \Delta_{PE}^2 N / \lambda^2$  occurs at metric wavelengths as a result of the longitudinal electric dipole effect. This compares with an enhancement  $\sim \epsilon^2 N$  for the charge excess mechanism, where  $\epsilon$  is the fractional charge excess. Putting  $\Delta_{PE} \sim 3 \times 10^{-4} \text{ m}$ , we find that the enhancement arising from the dipole mechanism for  $\lambda = 3 \text{ m}$  is  $\sim 10^{-7} N$  compared with  $\sim 10^{-1} N$  for the charge excess mechanism ( $\epsilon \sim 0.3$  assumed for 20 MeV electrons). Even with fields as high as  $10^4 \text{ V m}^{-1}$  ( $\Delta_{PE} \sim 3 \times 10^{-2} \text{ m}$ ) the dipole enhancement only rises to  $10^{-3} N$ .

We therefore conclude that, of the two types of charge separation by the electric potential gradient of the atmosphere, only the transverse separation is capable of producing yields of radio emission from extensive air showers which are comparable with those produced by the geomagnetic charge separation and charge excess mechanism. Both the direction and the amount of the electrically produced charge separation will depend on the local atmospheric electric field along the shower track and thus the magnitude and polarization of the radio emission produced by the mechanism will vary widely with local climatic and other factors. This may reduce the usefulness of the observed intensity of radio emission as a measure of the size of the extensive air showers.

### Small Angle Filtered Electron Diffraction from Growing Films

WE have developed a method for studying the structure of thin films during the earliest stages of growth. The method is based on small angle electron diffraction<sup>1-3</sup> and is more sensitive than *in situ* electron microscopy.

At early stages of film growth the resolving limit for *in situ* microscopy is set by lack of contrast<sup>4</sup>. When silver is deposited, to an average thickness of about 10 Å on carbon in good vacuum conditions, the resolving limit is 20 Å (ref. 5). At this stage the films consist of globular well developed islands. The elastically scattered small angle ( $s \sim 0.01 \text{ Å}^{-1}$ ) intensity profile is proportional to

$$I(s) = N \bar{n}^2 f^2(s) \exp \left( -\frac{4}{3} \pi^2 s^2 \bar{R}_g^2 \right) \left[ 1 + \frac{\sigma_n^2}{\bar{n}^2} - \frac{P J_1(2\pi s r_0)}{2\pi s r_0} \right] \quad (1)$$

where  $s = 2 \sin \frac{1}{2} \beta / \lambda$ ,  $N$  is the number of islands irradiated,  $\bar{n}$  is the mean number of atoms per island,  $\bar{R}_g$  is the mean radius of gyration of an island and  $\sigma_n^2$  is the variance of  $n$ .

If the number of island centroids lying between  $r$  and  $r + dr$  from an arbitrary origin is  $2\pi r \rho(r) dr$ , then  $\rho(r)$  is found to be nearly a step function  $\rho(r) = 0$ ,  $r < r_0$ , and  $\rho(r) = \rho_0$ ,  $r \geq r_0$ ; the dimensionless parameter  $P = 2\pi r_0^2 \rho_0$ .

Equation (1) applies only to the scattering from the growing film; scattering from the substrate adds a profile of its own, measured before deposition is begun. Conditions are of course kinematic.

Recordings made during the growth of a silver film on to carbon, inside a scanning electron diffraction system, are shown in Fig. 1 with points calculated using equation (1). One difficulty is that the intensity profiles can be approximated by a cubic equation, whereas equation (1) contains five unknown parameters  $N\bar{n}^2$ ,  $\bar{R}_g$ ,  $\sigma_n$ ,  $\rho_0$  and  $r_0$ . It is found by trial in computer curve-fitting that the uncertainties in  $(\sigma_n/\bar{n})^2$  and  $P$  do not greatly affect the values determined for  $\bar{R}_g$  and  $r_0$ . The earliest stage of film growth for which useful results have so far been obtained is when the film's average thickness was 0.75 Å when  $\bar{R}_g = 8.3 \pm 1$  Å and  $r_0 = 33 \pm 8$  Å. The accuracy of the method has been checked by comparing the values obtained for  $\bar{R}_g$  and  $r_0$  for much thicker films, about 10 Å average, with values obtained from electron micrographs.

Fig. 1. Growth of silver on to carbon. The evaporation proceeds for 15 sec and is then stopped by a shutter while the intensity profile is recorded, and so on. Successive increments of average film thickness are 0.75 Å. 30 keV electrons, filtered 0.2 eV. The plotted points were obtained by curve fitting to equation 1.

Fig. 2. Filtered and unfiltered diffraction profiles of 5 Å silver film on carbon substrate (200 Å). Filtered profile consists largely of elastically scattered electrons, unfiltered profile contains up to 250 eV loss electrons.

Previous work<sup>3</sup> has not emphasized the importance of using well filtered electrons or has ignored it<sup>1,2</sup>. A profile consisting largely of elastically scattered electrons compared with a virtually unfiltered profile containing electrons which have lost up to 250 eV energy is given in Fig. 2. Clearly if quantitative deductions are to be made well filtered data must be used. An earlier attempt<sup>3</sup> at the derivation of equation (1) omitted the exponential factor; as a consequence the theoretical profiles bore scant resemblance to the observed ones; moreover a different distribution function was used<sup>3</sup> which required well resolved micrographs for determining it and the assumption of spherical islands.

The advantage of this method of studying film growth is that statistical data may be obtained for films so thin that nothing quantitative can be obtained by *in situ* electron microscopy. The high sensitivity is explained by equation (1), which shows that in the small angle region  $I(s)$  is proportional to  $\bar{n}^2$ , while in electron microscopy the contrast is related to  $\bar{n}$  and in normal electron diffraction the intensity is proportional to  $\bar{n}$ .

### Quasi-linear Dispersion Spherical Fabry-Perot Interferograms for Giant Pulse Laser Spectroscopy

SPHERICAL interferometer fringes have previously been considered unsuitable for the production of a spectrum extending over several orders of the spectral range, chiefly because when the spherical mirrors are separated by exactly their radius of curvature<sup>1,2</sup>, the order of interference of the fringe pattern decreases as the fourth power of the radius. (With a plane Fabry-Perot instrument, the order of interference varies with the square of the radius.) In practice, however, spherical interferometers have been used successfully to measure the time resolved spectra of ruby laser relaxation oscillations<sup>3</sup> and, more recently, for the direct spectral detection of off-axis modes in giant pulse ruby lasers<sup>4</sup> and an intensity dependent frequency shift<sup>5</sup>. In circumstances like these the spherical instrument has the advantage of the high intensity of the illumination of the detector and the fact that the plates are always well adjusted.

The fringes visible in the spherical interferometer are the spherical aberration diffraction pattern of the mirrors, sharpened by multiple reflexions. It is for this reason that they can only be seen when the instrument is illuminated by a monochromatic axial point source or by the equivalent laser wavefront. It is well known that the spherical aberration diffraction patterns of optical elements are radically altered<sup>6-8</sup> by the addition of a defocusing term.

The structure of the interference fringe pattern for a particular mirror separation is most easily calculated by considering the optical path difference between successively reflected rays as a function of the ray zonal radius. Fig. 1 represents an incoming plane wavefront, represented by the rays *AB*, *CD*, *EF*, passing through an interferometer consisting of two high reflectivity spherical mirrors of equal radii of curvature (*R*) and separated by the distance *EF*. *AB* and *CD* are parallel to and equidistant from the axial ray *EF* passing through

the centres of curvature of the symmetrically arranged mirrors.  $ABCDAB$  represents, to a first approximation, the path of a reflected ray and it is easily shown<sup>1,2</sup> that the total optical path difference between this reflected ray and the directly transmitted ray  $AB$  has the value

$$4(R + \rho) - (r^4/R^3) - (4\rho r^2/R^2)$$

where  $AC = BD = 2r$  and  $EF = R + \rho$ , and where  $\rho$  can be a positive or negative distance. The condition for constructive interference is then given by

$$4(R + \rho) - (r^4/R^3) - (4\rho r^2/R^2) = m\lambda \quad (1)$$

so that the relative positions of the fringes in the diffraction pattern are determined by the values of  $\rho$  and the zonal radius  $r$ .

If a "fringe number"  $p$  is defined by the relation

$$p\lambda = (r^4/R^3) + (4\rho r^2/R^2) \quad (2)$$

then  $p$  is zero for the confocal case  $\rho = 0$  when  $r = 0$ , corresponding to the axial ray  $EF$ . For the non-confocal arrangement, the fringe number is also zero, to fifth order terms in  $(r/R)$  and first order terms in  $(\rho r^2/R^2)$ , when

$$r^2 + 4\rho R = 0 \quad (3)$$

Differentiation and rearrangement of (1) give  $d^2\lambda/dr^2 = 0$  and  $d\lambda/dr$  constant for

$$r^2 + (2/3)\rho R = 0 \quad (4)$$

Choosing a suitable negative value for  $\rho$  to satisfy relation (4), a linear wavenumber dispersion with zonal radius, and hence with fringe radius, is obtained in the region of  $r = (-2\rho R/3)^{1/2}$ .

Adjusting relations (1), (3) and (4) to take into account the diverging lens effect of the plano-concave spherical mirrors (10 cm radius of curvature) used, and putting  $\rho = 150\mu$ , then  $r = 2.7$  mm—a convenient input zonal radius for a typical 1 cm diameter giant pulse laser beam. The linear dispersion position in the fringe field then corresponds to an output zonal radius  $r_0 = 4$  mm for this 10 cm interferometer, well within the 2.5 cm diameter mirror apertures. (The fringe number  $p$  is zero at  $r_0 = 7$  mm.) The resulting fringe pattern is illustrated in Fig. 2, showing an interferogram of three axial modes of a helium-neon gas laser ( $\lambda 6328$ ), the neighbouring axial modes of which are separated by 175 Mc/s (cavity length 85 cm). The second and third sets of three fringes, counting outwards from the centre of the pattern, are located in the linear dispersion region. Calculation<sup>3</sup> shows that the dispersion should be linear there to within 2 per cent over a frequency spread of 500 Mc/s, and this is verified by measurement of the interferogram. (Whatever the magnitude of the lens effect of the mirrors, the fractional change in the dispersion ( $d\lambda/dr$ ), for a fractional change  $kr$  in the zonal radius  $r$ , is given by

$$\Delta(d\lambda/dr)/(d\lambda/dr) = k^2(k+3)/2.)$$

Fig. 1. Ray paths through spherical interferometer.

Fig. 2. Three axial modes of 85 cm gas laser ( $\lambda 6328$ ).

Fig. 3. Dispersion calibration curve of 10 cm interferometer for  $\rho = -150\mu$ , derived from Fig. 2.

As can be seen from the dispersion calibration curve (Fig. 3) obtained from microdensitometer traces of the etalon interferogram, linearity is, in fact, largely preserved over a spectral spread considerably greater than the free spectral range of the interferometer (750 Mc/s). For image tube and multi-channel photoelectric detection of laser spectra, particularly if ultra-fast time resolution of giant pulses is required, matching of the interferogram to the spatial resolution of the detector<sup>10</sup> is straightforward and, more important, quantitative interpretation of small frequency shifts is possible.

Several spherical Fabry-Perot interferometers of various separations are now being evaluated in this laboratory for ruby and neodymium giant pulse laser diagnosis<sup>9</sup>. The simple optical path difference calculation described here has been found adequate in determining the value of the optimum separation so as to place the linear dispersion region in the most useful part of the interferogram, usually at a zonal radius corresponding to half the exit aperture radius. (Various laser beam diameters can be

dealt with for this value of  $\rho$  by using the appropriate degree of telescopic magnification or demagnification of the beam aperture.) To determine the instrumental profile and finesse more precisely a computer wavefront calculation is being carried out, and the effects of coherent and incoherent illumination are also being studied.

The interferogram of Fig. 2 was photographed by Mr M. E. Engwell and the calibration curve was derived by Mr A. Durrant. This work is supported by the Science Research Council.

## Relativistic Equations of State

WE offer a new approach to an old<sup>1</sup> question: "Given a material medium with its equation of state, what conditions must be satisfied by that equation of state if the existence of such matter is to be consistent with the principles of special relativity?" Our object is to determine one such condition. Our approach has the advantage that it is not necessary to consider the detailed structure of the matter, but it has the disadvantage that it is not applicable in its present form to the most interesting case—that of nuclear matter at high densities.

The two traditional approaches to this question may be summarized as follows:

(1) It has been claimed<sup>2</sup> that the assumption of causality\* implies that  $dp/d\rho \leq 1$ , where  $p$  is the pressure and  $\rho$  is the mass density of a fluid. (We have set  $c=1$ .) This inequality may be shown to hold rigorously for a perfect fluid characterized only by the two parameters  $p$  and  $\rho$ , with conserved stress-energy  $T_{\alpha\beta} = (p + \rho)\xi_\alpha\xi_\beta + p g_{\alpha\beta}$ . (Here,  $\xi_\alpha$  is the unit 4-velocity of a fluid element at each point.) Real matter, however, is more complicated. One must also consider temperature, composition and possibly other variables—the equation of state may, for example, depend on the past history of the matter. When these detailed properties of the matter are taken into account, no simple conclusion such as  $dp/d\rho \leq 1$  can be drawn.

(2) It has been claimed<sup>3</sup> that the "reasonable physical assumption" that the behaviour of high-energy particles is similar to that of photons implies that  $p \leq (1/3)\rho$  for all matter. This inequality is in fact satisfied for the case of a relativistic gas of non-interacting particles<sup>4</sup>. There is, however, no compelling reason why the equation of state for a gas of non-interacting particles should approximate that for matter (see, for example, the discussion of Zeldovich<sup>5</sup>).

Our approach may be illustrated by a simple example based on a spring characterized by the following three parameters: unstressed length =  $L$ ; mass per unit length =  $\rho$ ; spring constant  $\times$  length =  $p$ .

We assume energy conservation and causality. Accelerate the spring to a velocity  $v < 1$  so that, during the acceleration process, the length of the spring in its own rest frame is kept constant. We wish to entrap the spring

in a cylindrical container of length  $b$ , closed at the rear and with a sliding door at the front. At the moment the leading end of the spring strikes the rear of the container, a light signal is sent along the spring. If the

length  $b$  is chosen to be  $L \frac{\sqrt{1-v^2}}{1+v}$ , then this signal reaches

the trailing end of the spring just as this end enters the container. The sliding door is then shut. Thus the assumption of causality, which entails that the information that the leading end of the spring has struck the container does not reach the trailing end of the spring faster than light, determines the size of the container necessary to entrap the spring. After the spring has settled down and cooled off, the container is opened and the spring is allowed to expand. The energy released in this expansion is carefully collected. The requirement that the energy necessary to accelerate the spring should be greater than or equal to that released by the expansion is

$$\rho \left( \frac{1}{\sqrt{1-v^2}} - 1 \right) \geq \frac{1}{2} p \left( 1 - \frac{\sqrt{1-v^2}}{1+v} \right)^2$$

This inequality will hold for all  $v < 1$  if, and only if,

$$\rho \geq p$$

One would hope to apply a similar argument to nuclear matter at high densities. There is, however, a serious difficulty: it is necessary to introduce a second container to hold the matter under high pressure during the acceleration process. In order to obtain the inequality  $p \leq \rho$ , it is now necessary to find a *gedanken* procedure to recover the energy involved in accelerating this second container.

## States in Neon-21 near 3 MeV

PROPERTIES of low lying levels of neon-21 have been the subject of extensive studies<sup>1-8</sup> in recent years and the strong coupling collective model with K band mixing has been used for their interpretation<sup>2,4,6,9,10</sup>. Two states, which are predominantly members of  $K=1/2$  and  $K=3/2$  rotational bands and have  $J^\pi=1/2^+$  and  $9/2^+$  respectively, are predicted<sup>9,10</sup> near to 3 MeV excitation in neon-21. In addition, Freeman<sup>10</sup> has predicted a  $J^\pi=5/2^+$  state near 3 MeV and a  $3/2^+$  state near 3.5 MeV, while Davidson<sup>9</sup> shows three states of  $3/2^+$ ,  $1/2^+$  and  $5/2^+$  between 3.5 and 4 MeV. In this calculation an additional  $K=1/2$  band, based on Nilsson orbit 6, was included.

Recent high-resolution  $\gamma$ -ray studies<sup>7,8</sup>, using the reactions  $^{18}\text{O}(\alpha, n\gamma)^{21}\text{Ne}$  and  $^{20}\text{Ne}(d, p\gamma)^{21}\text{Ne}$ , have established a doublet in neon-21 at 2.791 and 2.797 MeV. The latter state has been shown<sup>8,11</sup> to be  $J^\pi=1/2^+$  as the former is not populated in the reaction  $^{20}\text{Ne}(d, p\gamma)^{21}\text{Ne}$ .  $J^\pi=1/2^+$  was also suggested for the 2.791 MeV state by Pelte *et al.*<sup>4</sup> from an application of the  $(2J+1)$  rule to the averaged  $^{23}\text{Na}(d, \alpha)^{21}\text{Ne}$  cross-sections. He subsequently explained<sup>12</sup> the reduced M1 transition probabilities from the 2.791 state by accepting this assignment which was based on a hole in Nilsson orbit 6. Bent *et al.*<sup>6</sup> were unable to explain this hindrance on the assumption of  $5/2^+$ .

\* This implies that if initial data for any system are given on a space-like surface  $S$ , the state of the system at any point  $P$  of space-time is uniquely determined by the data on the intersection of  $S$  with the interior of the backward light cone of  $P$ .

Fig. 1. Distorted wave  $l=0$  and  $l=2$  angular distribution fits to the 2.791/2.797 and 2.87 MeV "triplet" in the reaction  $^{22}\text{Ne}(^3\text{He}, \alpha)^{21}\text{Ne}$  at  $E(^3\text{He}) = 9.744$  MeV (lab.). The optical model parameters used are shown.

Thus it seemed likely that both members of the 2.80 MeV doublet were  $J^\pi = 1/2^+$  states. A more recent study<sup>13</sup> of  $\gamma$ - $\gamma$  and  $n$ - $\gamma$  angular correlations from the reaction  $^{18}\text{O}(\alpha, n\gamma)^{21}\text{Ne}$ , however, gives very strong evidence for an assignment of  $J = 3/2$  to the 2.791 MeV state. This experiment also confirms that  $J = 9/2$  for the state at 2.87 MeV. Thus the other possible spin allowed previously<sup>4-6</sup>, namely  $J = 5/2$ , can now be eliminated.

In the present experiment, a study of the reaction  $^{22}\text{Ne}(^3\text{He}, \alpha)^{21}\text{Ne}$  was undertaken to test the validity of the Nilsson model description of neon-21. The angular distribution shown in Fig. 1 corresponds to the unresolved group of the three states discussed here. It was analysed by the DWBA using the code DRC<sup>14</sup>. Fig. 1 shows the DWBA calculations for both  $l=0$  and  $l=2$  angular momentum transfers. The optical model potentials and cut-off radius are identical to those used by us in the analysis of the angular distributions for the ground state and first excited state of neon-21. The calculations clearly indicate an  $l=2$  transition, the contribution from an  $l=0$  transition being, apparently, negligible. This  $l=2$  transition indicates either a  $J^\pi = 3/2^+$  or  $5/2^+$  state. Thus the present experiment is consistent with the latest  $3/2$  assignment to the 2.791 MeV state<sup>13</sup> and, further, indicates that it is a positive parity state.

A similar measurement has been carried out at 15 MeV (C. M. Fou, personal communication) and preliminary analysis also indicates  $l=2$  for the transition.

## CHEMISTRY

### Initiation of the Hydrogen Chlorine Reaction by Red Laser Light

DURING a recent discourse at the Royal Institution<sup>1</sup>, I wished to illustrate the effect of  $Q$  switching on the peak intensity of light emitted by a pulsed ruby laser and also to demonstrate the occurrence of intensity dependent two quantum processes. This was achieved in a simple and striking manner by using the best known of all photochemical demonstrations, the hydrogen chlorine explosion.

When a pulse from a ruby laser, of energy 30J, was projected across the theatre and focused onto a vessel containing hydrogen and chlorine at a total pressure of 1 atm., no reaction was observable, nor was any reaction expected because chlorine is transparent to the red light of the ruby laser which emits at 6943 Å. When the experiment was repeated with no change in the arrangement except for the interposition of a cell containing cryptocyanine dye between the laser rod and the mirror, the characteristic explosion of hydrogen and chlorine occurred.

The cryptocyanine  $Q$  switch reduces the total energy output of the laser pulse by a factor of ten and the effect must therefore be attributed to the increased intensity of the 20 nsec pulse which is emitted under  $Q$  switched conditions. The process of two quantum absorption which is proportional to the square of the intensity will therefore be greatly increased when the  $Q$  switch is inserted.

The two quantum process is equivalent to absorption of a quantum of wavelength 3476 Å, which is near to the first absorption maximum of molecular chlorine and is known to lead to dissociation. Although similar two quantum processes have been observed in systems where an intermediate energy level is available<sup>2</sup>, the chlorine system seems to be a clear case of a gaseous photochemical reaction induced by true frequency doubling.

I thank Mr M. Topp for invaluable help with the experiments.

### Purification of the Optical Antipodes of $\alpha$ -Arylalkylamines by the Formation of Clathrates

THE classical methods for resolving amines such as  $\alpha$ -phenylethylamine<sup>1,2</sup>,  $\alpha$ -(*p*-tolyl) ethylamine<sup>3,4</sup>, or  $\alpha$ -phenylpropylamine<sup>4</sup> into their optical antipodes involve salt formation with a naturally occurring acid such as *d*-tartaric or *d*-camphoric acid. By these methods, one of the antipodes can usually be isolated in a pure state by successive crystallizations of the less soluble diastereoisomeric salt. The antipode remaining in the mother liquor, however, is always contaminated by the other and another resolving agent is necessary for further purification. Theilacker<sup>1</sup> has purified *d*- $\alpha$ -phenylethylamine by sulphate formation; we did not, however, obtain the same result with other  $\alpha$ -arylalkylamines. In most cases, the isolation of *d*-amines by these methods requires the use of expensive reagents such as *L*-malic acid.

We have now found that the optical isomers of most  $\alpha$ -arylalkylamines can be efficiently purified through clathrate formation by their co-ordination complex  $[\text{Ni}(\text{NCS})_2(\alpha\text{-arylalkylamine})_4]$ . It is known that complexes of this type are used to form clathrates with a wide variety of aromatic compounds<sup>5-7</sup>. These clathrates can be formed simply by mixing an aqueous solution of nickel

thiocyanate with the stoichiometric amount of amine in the presence of an aromatic compound. The clathrate then separates as a crystalline precipitate. Another method is to react the corresponding diamine complex with two additional molecules of amine according to the following reaction, where *Ar* is the aromatic compound

We have observed that when this reaction is performed with an excess of amine in which one of the antipodes predominates, the amine co-ordinated into the clathrate is preferentially racemic. This phenomenon may be illustrated as follows, *d* and *l* representing the dextro and laevo isomer of the amine respectively

Thus by reacting the correct amount of complex with the amine to be resolved, the antipode in excess of the racemic composition will remain in the liquid medium from which it can be readily isolated. To obtain this antipode in a pure state, it is obviously necessary that the whole of the other should be co-ordinated into the clathrate. The operating variables such as temperature, contact time, nature of the aromatic compound, etc., should therefore be adjusted in order that the reaction may go to completion. For example, the aromatic compound which will be selected should form the most stable clathrate. For the same reason it is advisable to use an amount of diamine complex somewhat in excess of the stoichiometric quantity with respect to the racemic amine to be removed.

In a typical experiment, 3.75 mmoles of the complex  $[\text{Ni}(\text{NCS})_2(\text{dl-}\alpha\text{-phenylethylamine})_2]$  was added to 30 ml. of *t*-butylbenzene containing 12.66 mmoles of  $\alpha$ -phenylethylamine enriched to 75 per cent in the *d*-isomer ( $[\alpha]_D = +20.15^\circ$ ). After stirring for 10 min at  $0^\circ \text{C}$ , the resulting clathrate was filtered off. The filtrate was diluted with 40 ml. of *n*-heptane in order to precipitate any dissolved complex which was removed by a second filtration. The unreacted amine was extracted from the filtrate with 3 ml. of 20 per cent sulphuric acid and then liberated by neutralization with 12 ml. of 20 per cent sodium hydroxide. Its specific rotation was found to be  $+38.10^\circ$  which corresponds to an optical purity of 97.3 per cent based on the value  $+40.3^\circ$  as stated in the literature for optically pure  $\alpha$ -phenylethylamine<sup>1</sup>.

It is noteworthy that the selective co-ordination of racemic amine as demonstrated by the preceding example can only be observed when clathration takes place. Thus by substituting *n*-heptane for *t*-butylbenzene in a similar experiment, the unreacted amine was only 64 per cent in the *d*-isomer.

Table 1. PURIFICATION OF *d*- $\alpha$ -ARYLALKYLAMINES BY THE FORMATION OF CLATHRATES

Amine	Clathrated compound	<i>d</i> -Antipode purity (per cent)	
		Initial	Final
$\alpha$ -Phenylpropylamine	Methylnaphthalene*	67.8	92.7†
$\alpha$ -( <i>m</i> -Chlorophenyl)ethylamine	<i>p</i> -Xylene	79.6	99.2‡
$\alpha$ -Phenylisohexylamine	<i>m</i> -Xylene	71.2	94.0§

\* Percentage of isomers:  $\alpha$ -, 57;  $\beta$ -, 43.

† Based on  $[\alpha]_D = 20.20^\circ$ , highest specific rotation found in the literature for the optically pure *d*-amine<sup>1</sup>.

‡ Based on  $[\alpha]_D = 26.35^\circ$ , highest specific rotation obtained for the *l*-amine by successive crystallizations of its *d*-tartrate.

§ Based on  $[\alpha]_D = 10.50^\circ$ , highest specific rotation obtained for the *l*-amine by successive crystallizations of its *d*-camphorate.

Table 1 shows some results obtained with other  $\alpha$ -arylalkylamines. In each case, the sample treated was the residue of the *l*-antipode isolation from racemic amine by modifications of classical methods using *d*-tartaric or *d*-camphoric acid as resolving agent. These results show that, by the present method, high optical purity can be reached in only one step even from rather impure samples. Obviously the same procedure may be applied to the purification of both antipodes. For instance, the impure *l*-antipode first crystallized as the salt of *d*-tartaric or *d*-camphoric acid may be purified in the same way. Thus

by combining the present method with a crude resolution effected by any conventional means, both antipodes can be isolated in pure form without resorting to numerous crystallization steps.

Clathrates resulting from this procedure can be thermally decomposed by reversing the reaction shown in equation (1), either by heating *in vacuo* or by stripping with a hot fluid at a temperature depending on the nature of the co-ordinated amine<sup>5</sup>. The diamine complex is thus regenerated and the liberated racemic amine may be further treated for optical resolution.

## A New Series of Isoprenoid Isoalkanes in Crude Oils and Cretaceous Bituminous Shales

In recent studies on the origin of petroleum much emphasis has been laid on the structural relationship between compounds occurring in petroleum and their possible natural precursors. A series of compounds, now well known as the isoprenoid isoalkanes, has received much attention, partly because of their sometimes strikingly high concentrations, partly because of their possible relationship to phytol. The members of the 2,6,10-trimethyl- and 2,6,10,14-tetramethylalkane series with 14 (ref. 1), 15 (ref. 1), 16 (ref. 2), 18 (ref. 2), 19 (ref. 3), 20 (ref. 4), and 21 (ref. 2) carbon atoms have been reported. The member of the 2,6,10-trimethylalkane series with seventeen carbon atoms proved either to be absent or to occur at best in only very small amounts<sup>5</sup>.

Johns *et al.*<sup>6</sup> have reported the occurrence of series of isoalkanes (2-methylalkanes), ante-isoalkanes (3-methylalkanes) and *n*-alkylcyclohexanes in shales and oils of very different ages ( $2.7 \times 10^9 \text{ yr} - 3 \times 10^6 \text{ yr}$ ). They discuss the possible relationship of these compounds to presumed natural precursors.

During a study of the gasoline/kerosene-range hydrocarbons from marine bituminous shales of Cretaceous age from Italy, our attention was attracted by a number of conspicuous peaks in the capillary gas chromatograms. (The hydrocarbons were liberated by stripping the rocks with carbon dioxide at  $150^\circ \text{C}$  for 1 h, and collected above a 40 per cent potassium hydroxide solution.) Regularities in the gas chromatograms suggested two homologous series (see Fig. 1). Two-stage gas-liquid chromatography in series with a mass spectrometer<sup>7</sup> revealed that some of these peaks could be attributed to the series of isoprenoid 2,6,10-trimethylalkanes and others to a series of 2,6-dimethylalkanes. The member of the last series containing nine carbon atoms had already been reported in 1958 (ref. 8) and the member with ten carbon atoms has been isolated from petroleum by Mair *et al.*<sup>9</sup>. We identified the members with 9, 10, 11, 12, 13 and 14 carbon atoms.

Fig. 1. Gas chromatogram of the volatiles liberated from a Cretaceous rock sample from Italy. 200 m copper capillary column coated with squalane. Starting temperature 30° C, rising by 37.5° C/h up to 140° C, then constant. Inlet pressure 1.5 atm, linearly increasing by about 1 atm./h up to 5.1 atm., then constant. Chart speed 24 in./h.

Our identification is based on data from gas-liquid chromatograms (see Figs. 1 and 2) and mass spectra (see Fig. 3).

The gas chromatograms reveal constant differences in the retention time for the *n*-alkanes as well as for the peaks under investigation. This indicates that these peaks may belong to a homologous series. The mass spectra show: (1) that the elemental compositions are  $C_nH_{2n+2}$ , where  $n=9-14$ ; (2) that the identity of the  $C_9$  compound is 2,6-dimethylheptane, as found by comparing the spectrum with American Petroleum Institute spectra; (3) relatively high intensities of fragments with eight carbon atoms and of fragments with ( $n-6$ ) carbon atoms, especially of  $C_{n-8}H_{2n-12}$ ; (4) relatively low intensities of fragments with more than eight carbon atoms.

These data strongly indicate a homologous series and that the structure of all compounds is  $C_6-C(C)-C_{n-8}$  containing more branches than the one already indicated.

Furthermore, we conclude from the fragmentation pattern that the  $C_6$  and  $C_{n-8}$  chains cannot contain quaternary carbon atoms and that the third or higher numbered carbon atoms in the chains cannot be tertiary carbons. Gas chromatographic retention data show that the unknown peaks cannot be ascribed to monomethyl-substituted alkanes. We can preclude 2,6, ( $n-1$ )-trimethyl-substituted alkanes containing 11, 12, 13 and 14 carbon atoms because of the relatively low intensities of the ( $n-1$ ) fragments. This is confirmed by the fact that the retention time of 2,6,10-trimethylundecane is shorter than that of the unknown  $C_{14}$ -compound.

Fig. 2. Part of a gas chromatogram of saturates from paraffinic Nigerian crude oil. 100 ft. stainless steel capillary column coated with SE 30. Starting temperature 90° C, rising by 2° C/min up to 250° C. Chart speed 20 in./h.

Fig. 3. Mass spectra of 2,6-dimethylalkanes.

From the definite identification of the  $C_9$ -compound as 2,6-dimethylheptane and from the impossibility of a trimethyl substitution already mentioned, we concluded that the homologous series must be the series of 2,6-dimethylalkanes.

The "isoprenoids" in our Cretaceous rock samples are remarkable from a quantitative point of view (see Fig. 1). First, the isoalkanes of the 2,6-dimethyl- and 2,6,10-trimethyl series form together the bulk of the fraction boiling up to about 285° C; the *n*-alkanes up to  $n-C_{15}$  are only present in strikingly small amounts. Second, 2,6-dimethyldecane and 2,6-dimethyldodecane are present in

significantly smaller concentrations than two other members of the same series, namely 2,6-dimethylnonane and 2,6-dimethylundecane.

Having thus been put on the track of the 2,6-dimethylalkane series, we also looked for these compounds in crude oil. In fact, we were able to identify them as a number of rather pronounced peaks in the gas chromatogram of the saturates of a paraffinic Nigerian crude oil (see Fig. 2). The presence of these compounds is not limited to this particular crude oil because these peaks are also quite common in the chromatograms of other paraffinic crude oils.

Because the structure of the compounds under investigation is very specific and the amounts in which they occur are often relatively high, they must be hydrocarbons that were either present as such in the source material or have been derived from their precursors by processes that left the original carbon skeleton, or at least part of it, unchanged. For the isoprenoids pristane and phytane, phytol has been suggested as a possible precursor<sup>3</sup>. For the lower members of the series, a genetic relationship to phytol is possible, although they might also be derived from compounds of lower molecular weight such as farnesol or farnesene<sup>6,10</sup>.

For the formation of the C<sub>17</sub> 2,6,10-trimethylalkane and the C<sub>12</sub> and C<sub>14</sub> 2,6-dimethylalkanes, not only a cleavage of a C-C bond of the chain is necessary, but also the splitting off of a methyl group<sup>5</sup>. This reaction is unlikely, however. The relatively low concentrations often found for these compounds might be seen to be in accordance with the lower probability of their formation from phytol.

On the other hand, other precursors for these and possibly other isoprenoid isoalkanes should also be looked for. Squalene shows a carbon skeleton from which many isoprenoid isoalkanes can be thought to have been formed. Another source might be found in the carotenoids. Both types of compound have been suggested earlier as precursors for petroleum hydrocarbons<sup>2,5,6,9,10</sup>. Van Hoeven *et al.*<sup>11</sup> have isolated two isoalkanes from an Australian oil, which they think to be 5,9- and 4,9-dimethyltetradecanes. They suggest that these isoalkanes may have originated from squalene. For example, from the carotenoids  $\beta$ -carotene has been suggested by Mair as the source of the compound 1,1,3-trimethylcyclohexane<sup>10</sup>. In this respect it is interesting to note the recent mention<sup>12</sup> of carotane in a Green River oil shale extract.

It seems quite reasonable to assume also that either squalene or the carotenoids or both have to be considered as the precursors of the 2,6-dimethylalkane series, described in this communication.

## Synthetic Analogues of Polynucleotides: Interaction of a Polymeric Adenine Derivative with DNA

ANALOGUES of polynucleotides in which the naturally occurring bases are partly or completely replaced by analogues have been synthesized *in vivo* and by enzyme methods<sup>1,2</sup>. It appeared to us to be of interest, however, to synthesize polymers soluble in water which could be considered as analogues of polynucleotides in the possession of side chains of purines and/or pyrimidines but in which the backbone would not be composed of sugar residues linked by phosphodiester linkages. Previous work in this laboratory has already shown that a polymer of this type can be formed by copolymerizing 5'-O-acrylyl-uridine with acrylamide and that this polymer interacts with DNA in solution<sup>3</sup>; the polymer was obtained by polymerization of a suitable monomer containing a pyrimidine. We now report the synthesis of a similar type of polymer by the linking of a purine derivative and a pre-formed polymer, polyacrylic acid hydrazide<sup>4</sup>. The polymer was treated with the dialdehyde obtained by the periodate oxidation of adenosine, and gave a polymer containing adenine, a fraction of which was found to hybridize with denatured DNA in solution.

The polymer was prepared as follows. Polyethyl acrylate was prepared by polymerizing ethyl acrylate (3 ml.) in dry dioxan (30 ml.) at 60° C for 48 h with azobisisobutyronitrile (50 mg) as initiator. The resulting polymer was isolated and treated for 10 h in an oil bath at 140° C with 90 per cent hydrazine hydrate. The reaction solution was diluted with water, exhaustively dialysed against distilled water and freeze-dried to give polyacrylic acid hydrazide (2 g). (Found (after drying at 110° C *in vacuo*), C, 41.40; H, 6.90; N, 28.7 per cent. Calc. for C<sub>3</sub>H<sub>6</sub>N<sub>2</sub>O, C, 41.90; H, 7.02; N, 32.06 per cent.)

Sodium metaperiodate (126 mg) was added to a solution of adenosine (140 mg) in water (140 ml.). After 1 h at room temperature the solution was added to a solution of polyacrylic acid hydrazide (420 mg) in water (280 ml.) and left at room temperature for 24 h. The solution was dialysed against three changes of water. The resulting cloudy solution was centrifuged and the sediment freeze-dried to give an insoluble product (96 mg). A portion of the solution of the soluble polymer was freeze-dried to give a product which contained 13.4 per cent of adenine (determined on material dried at 110° C *in vacuo* by acid hydrolysis and separation of the adenine by paper chromatography). (Found, N, 32.0 per cent. Calc., N, 31.5 per cent.) The freeze-dried sample did not redissolve completely in water, so the bulk of the polymer (equivalent to 480 mg dry weight) was stored in solution. The proportion of insoluble to soluble polymer formed increased when the reaction was carried out in pH 4.6 and pH 7 buffers and when more adenosine dialdehyde was used.

The structure of this polymer has not been determined, but it would appear from the reaction of isonicotinic acid hydrazide with periodate oxidized RNA that the dialdehyde would react with only one hydrazide residue<sup>5</sup>. If this is so, analysis indicates that the polymer contains approximately one adenine residue for each 8 acrylic acid hydrazide residues. The molecular weight of the polymer was estimated by gel filtration on 'Sephadex'. About 55 per cent was excluded from both 'Sephadex G-200' and 'G-100'. The shape of the elution pattern indicated that both a high molecular weight fraction (> 2 × 10<sup>5</sup>) and a low molecular weight fraction (≤ 10<sup>5</sup>) were present. One explanation of this might be that cross linking had occurred because of the reaction of some dialdehyde residues with hydrazine residues on different polymer chains. A similar distribution of molecular weight was, however, observed with a polymer formed by the reaction of vanillin with polyacrylic acid hydrazide, so it is more probable that the effect is due to the molecular weight distribution of the polyacrylic acid hydrazide.

The interaction of the polymer with denatured DNA was carried out using the DNA-agar gel technique introduced by Bolton and McCarthy<sup>6</sup>, modified as previously described<sup>3</sup>. The results (Fig. 1) showed that 9 per cent of the polymer was retained by the DNA-agar at high salt concentration and was eluted at low salt concentration. When it was hydrolysed with alkali, this fraction gave adenine (corresponding to 75 per cent of the ultra-violet absorption of the fraction); DNA was not hydrolysed in these conditions. This showed that the fraction contained less than 15 per cent of DNA. Control experiments showed that none of the polymer was retained by agar alone. The fraction of the polymer eluted at low salt concentration was tested for its ability to hybridize

with denatured DNA in solution. The results (Fig. 2) showed that there was a maximum hypochromic effect of about 16 per cent after the mixtures had been kept at room temperature for 24 h; after standing for 4 h the hypochromic effect was about 7 per cent.

These results therefore extend those already obtained with the copolymer of 5'-O-acetyluridine and acrylamide. They show that certain polymers which contain non-nucleotide backbones and purine or pyrimidine side chains are able to interact with denatured DNA and might therefore have important effects in biological systems.

## Temperature Effects in Membrane Phenomena

THERMAL anomalies occurring over relatively narrow ranges have been described for many properties of water and aqueous solutions. In some cases only one such thermal anomaly has been claimed to exist between the freezing and the boiling point of water<sup>1-3</sup>. Drost-Hansen, however, has proposed<sup>9-13</sup> the existence of at least four anomalies in this temperature range, namely, near 15, 30, 45 and 60° C. Unfortunately, detailed data on the effects of temperature on membrane phenomena are notably lacking in the literature; however, anomalous temperature effects in some membrane properties have been reported. We propose that these anomalies reflect structural changes of the water in or adjacent to the membranes.

An interesting study of temperature effects was made on an exceedingly simple membrane by Rosano, Doby and Schulman<sup>14</sup> (see also Sears<sup>15</sup>). The rate of transfer of salt and water across a non-aqueous, liquid phase was studied at a number of temperatures. The liquid was *n*-butanol, separating two aqueous phases of different electrolyte concentrations. Fig. 1 shows the rate of transport of sodium chloride across the butanol membrane. There is an abrupt change in the rate between 30° and 39° C. The results obtained for the rate of transfer of potassium chloride (Fig. 2) very closely resemble the data for the

Fig. 1. Log rate of diffusion (equals log rate of change of potential) of sodium chloride across a 'butanol membrane' as a function of reciprocal, absolute temperature. Data points: Rosano, Doby and Schulman<sup>14</sup>. Curve redrawn by the present authors.

Fig. 2. Log rate of diffusion (equals log rate of change of potential) of potassium chloride across a "butanol membrane" as a function of reciprocal, absolute temperature. Data points: Rosano, Duby and Schulman<sup>14</sup>. Curve redrawn by the present authors.

Fig. 3. Conductance of barium stearate multilayer membranes. Data by Nelson<sup>16</sup>.

transfer of sodium chloride, again revealing an abrupt change between 30° and 39° C.

A number of model membrane systems have been described<sup>16</sup> which relate to ionic transport in biologic systems, measured at closely spaced temperature intervals. A relatively wide range of membranes was used. This study disclosed the occurrence of several thermal anomalies. As an example, Fig. 3 shows the conductance of barium stearate multilayer membranes, suggesting a highly anomalous behaviour near 28°–32° C. It was speculated that this anomalous behaviour was the manifestation of a phase transition.

Thompson<sup>17</sup> studied the properties of a bimolecular phospholipid membrane and measured the resistance across this membrane at closely spaced temperature intervals. His results are shown in Fig. 4. One notices the large maximum near 23° C and a marked transition in the vicinity of 29°–30° C. We propose that the increase in resistance between 29° and 30° C is a reflexion of a change in water structure in or adjacent to the bimolecular membrane. Thompson independently suggested there may be a continuous aqueous phase across the membrane and that the anomalies may be caused by higher order phase transitions.

Finally, as an example of studies of temperature effects on a natural membrane, we mention two studies on the plasma membrane of the green alga, *Valonia*. Fig. 5 shows the results obtained by Blinks<sup>18</sup> on *Valonia macrophyssa*;

the ordinate is the potential difference across the membrane, the abscissa is the temperature. It is apparent that the values for the potential from 15° to 30° C are relatively constant, independent of temperature, while the E.M.F. increases both below 15° C and above 30° C. One of us carried out a similar study of a number of specimens of *V. utricularis* (collected in Tahiti by Professor Blinks). Again, we found potential across the cell to be relatively constant between 15° and 30° C (Fig. 6). An abrupt increase in potential was found above 30° C with an abrupt decrease below 15° C (the latter trend being opposite to the trend noted by Blinks using *V. macrophyssa*).

Fig. 6. Potential across the membrane of the alga *Valonia utricularis* as a function of temperature. Data by Thorhaug<sup>19</sup>.

While higher order phase transitions may be expected in some systems (such as some lipid systems), we propose that the general occurrence of anomalies in membrane properties near certain discrete temperatures is likely to reflect changes in the underlying water structures. That thermal anomalies have been observed with an *n*-butyl alcohol liquid membrane, cellulosic type membranes, bimolecular phospholipid membranes, and the plasma membrane of a living cell, suggest that these anomalies are caused by some common factor in these systems rather than by the specific effects of the matrix material. Because water is common to all the membrane systems enumerated above, and because the anomalies often occur at or near the temperatures for which the anomalies occur in the properties of bulk water and aqueous solutions, it is reasonable to suggest that the anomalies observed in such membrane systems are caused by structural changes in the water associated with the membranes. For further discussion of some of these aspects, see the articles by the senior author, in particular, regarding the observations made by Trapeznikov on palmitic acid monolayers and by Steinert and Haase on the properties of cellulose membranes.

## MOLECULAR STRUCTURE

### Super-helical Model for Nucleohistone

DNA is combined, as nucleohistone, with histone proteins in the chromosomes and nuclei of all cells except bacteria. It has been suggested that histones are involved in regulating gene function<sup>1,2</sup>. The molecular structure of nucleohistone is basic to the structure of chromosomes. X-ray diffraction<sup>3</sup>, and physical chemistry<sup>4,5</sup> studies, suggest a coiled molecular structure for nucleohistone which is compatible with results from electron microscopy<sup>6-8</sup>. This communication discusses a coiled-coil structure and new experimental evidence that is compatible with it.

X-ray diffraction patterns from fibres of nucleohistone at high relative humidity (about 92-98 per cent) consist of three groups of reflexions (Fig. 1a). These are

(a) reflexions from the DNA double helix within the nucleohistone complex; these are poorly oriented, indicating that the DNA molecules are not well aligned; (b) an equatorial reflexion at 60 Å ascribed to lipid impurity<sup>3,9</sup>; (c) a series of low-angle diffraction rings, or slightly meridionally oriented arcs, corresponding to spacings of approximately 110, 55, 35, 27, 22 Å; the spacing and intensity of the rings vary with the relative humidity of the specimen. The rings arise from structural features of nucleohistone which have dimensions greater than those of histone or DNA molecules alone, that is, the complex has a tertiary structure. Consideration of these spacings<sup>10</sup>, together with the semi-meridional orientation, suggests that the structure is a coiled-coil (super-helix). The coiling accounts for the DNA diffraction not being well aligned.

Fourier transform calculations for helical models indicate that the super-helix has pitch 120 Å and diameter 100 Å<sup>11</sup>. The X-ray data at various humidities, including those of Luzzati and Nicolaieff<sup>12,13</sup>, considered in detail give general support to the model, but some features of the data are not satisfactorily accounted for, and the model must therefore be regarded only as a working hypothesis. It is encouraging, however, that Davies<sup>7</sup> has, by electron microscopy, found in chick erythrocytes hollow rods of about 150 Å outside diameter. These could be coiled nucleohistone threads. Allowing 30 Å diameter for the threads, the super-helix diameter measured from the axial centre of the threads would be 120 Å, which is in satisfactory agreement with the value of 100 Å for this dimension suggested by the X-ray data.

We have obtained further experimental evidence supporting the proposed super-helical structure by systematic study of the changes in the X-ray diffraction pattern brought about by stretching and relaxing fibre specimens of nucleohistone from calf thymus. A typical set of diffraction patterns is shown in Fig. 1; five separate experiments gave the same result. Fig. 1a was obtained from a fibre of diameter 120 μ at 92 per cent relative humidity. The reflexions characteristic of DNA are poorly oriented and the characteristic low-angle rings at 36, 26, 22 Å are present. The second pattern (Fig. 1b) was obtained after the specimen had been re-wetted with distilled water to form a stiff gel, and then redrawn until its diameter was 70 μ. This pattern shows improved orientation of the DNA reflexions but the low angle rings are not visible. Fig. 1c is the pattern obtained after the same fibre had been re-wetted with distilled water, and then allowed to relax without tension. It shows all the features of the original pattern.

The disappearance on stretching of the low-angle rings and the appearance of a well-oriented DNA pattern seem

Fig. 1. Three X-ray diffraction patterns from the same fibre specimen of calf thymus nucleohistone, all at 92 per cent relative humidity. (a) From the fibre as originally drawn, with a diameter of 120 μ; (b) after re-wetting and further drawing, with a diameter of 70 μ; and (c) after further wetting and relaxing of tension, with a diameter of 100 μ.

to provide incontrovertible evidence that in native nucleohistone the molecules of nucleohistone are in some regularly folded configuration with the DNA molecules inclined to the fibre axis. Stretching destroys regular folding and aligns the DNA molecules along the fibre axis. No increase in the spacing of the low angle rings is observed on stretching; instead the rings are replaced by diffuse scatter: this shows that the folded structure does not stretch uniformly but breaks up and becomes irregular on stretching. The regular folding re-forms when the specimen is wetted and relaxed. The super-helical model is an obvious choice for the folded structure. The stretching experiments are entirely consistent with a super-helical model but do not eliminate other types of fold in which the DNA molecules are inclined to the length of the nucleohistone molecule.

We thank Professor Sir John Randall for facilities, Mrs Rowena Hope and Mr Z. Gabor for assistance, and Dr H. G. Davies for discussion. J. F. P. acknowledges receipt of a Medical Research Council scholarship.

### Attempt to locate the $\alpha$ -Helical Segments of Ribonuclease

IN recent communications concerning the tertiary structure of ribonuclease two very different space models of this molecule were presented<sup>1,2</sup>. I wish to point out that, in circumstances such as these, a choice can be made between alternative structures or details of structures by a method based on a statistical matching of a given sequence of amino-acids with the sequences of proteins of known tertiary structure<sup>3</sup>. This method has been refined (my unpublished work) so that for every amino-acid position along the chain which is analysed the probability of that amino-acid belonging to an  $\alpha$ -helical segment can be calculated.

This method seems to give results which agree with X-ray data in the case of the hen egg-lysozyme<sup>4,5</sup>, but still more controls are required before the general validity of the method can be tested.

The  $\alpha$ -helical segments of ribonuclease, according to Kartha *et al.*<sup>1</sup>, should be located in the regions 5-12, 28-35 and 51-58 of the chain, but by statistical analysis I have obtained high probability figures for the residues 1-9, 14-23 and 47-59 (see Fig. 1).

Because of the difficulties and uncertainties involved in the determination of the tertiary structure of proteins

Fig. 1. Diagram showing the helical probability of the amino-acids of the ribonuclease. The abscissa shows the position on the chain from the N- to the C-terminal, and the ordinate shows the probability of the residue being in  $\alpha$ -helical conformation. Note the strong signals in the regions 1-9, 14-23 and 47-59. The last stretch overlaps completely with the third helical segment indicated by Kartha<sup>1</sup>, and the first one overlaps only partially. There is no agreement for the second stretch.

I hope that this technique will be of some use in this kind of problem.

### Cross-linking of Gelatine by Dehydration

THE contribution of water to the stability of macro-molecular structures of biological origin is often difficult to assess. Besides its intrinsic theoretical interest<sup>1,2</sup>, this problem is of great practical importance in studies concerned with the preparation of single crystals of proteins<sup>3</sup> and nucleic acids from an aqueous mother liquor as well as in studies of such macromolecules in non-aqueous solvents<sup>4</sup>. For these reasons we believe that the detailed study of physicochemical changes which accompany the excessive dehydration of proteins and nucleic acids might be of considerable value. In this communication, we wish to report evidence that gelatine becomes covalently cross-linked when the water content falls below about 0.2 g/100 g protein.

Ossein gelatine having a weight-average molecular weight of about 300,000 was used in this work. The preparative procedure leading to this grade has been reported<sup>5</sup> and a number of dilute solution properties of this gelatine have been determined<sup>5,6</sup>. The glass transition temperature as well as the viscoelastic properties of films prepared from this grade of gelatine have also been reported<sup>5,7</sup>. We intend to show, however, that the observed behaviour of excessively dehydrated gelatine is apparently independent of source or preparative treatment.

The moisture content of gelatine samples was routinely determined using a modification of the procedure recommended by Eastoe and Courts<sup>8</sup>. The determination started with atmospheric oven drying at  $105 \pm 1^\circ \text{C}$  for 24 h and was followed by evacuation under a pressure of

$10^{-3}$  mm mercury at  $105^\circ \pm 1^\circ$  C over an additional 24 h. After such treatment, the weight reached a level which remained constant within  $\pm 0.05$  per cent even during control tests where the treatment under vacuum was extended over an additional 48 h. An independent determination of trace moisture content in gelatine by titration with the Fischer reagent could not be made because of the insolubility of gelatine samples which had been excessively dehydrated.

The solubility of gelatine films (about 1 g) of known moisture content was determined by immersing them in 50 c.c. of deionized water which was maintained at  $40^\circ \pm 0.2^\circ$  C. After immersion for 2 h, the portion of the film remaining undissolved had become a swollen, but coherent and distinct, mass. This mass was removed from the aqueous solvent by gentle suction and was exhaustively dehydrated by treatment in an atmospheric oven at  $105^\circ \pm 1^\circ$  C for 24 h followed by evacuation under  $10^{-3}$  mm mercury at the same temperature for an additional 24 h. The proportion of gelatine which had failed to dissolve was then computed and expressed as a percentage by weight of insoluble gelatine. It was observed that prolongation of the immersion time of films over several days did not significantly affect the proportion of gelatine which remained undissolved after the routine 2 h immersion test.

The relation between the moisture content of gelatine and its solubility in water was found using gelatine films 0.1 cm thick, which were prepared by casting. This simple procedure involved dissolution of gelatine powder of known moisture content in deionized water in aluminium dishes kept at  $65^\circ \pm 0.5^\circ$  C in an atmospheric oven. The initial protein concentration thereby attained was about 5 per cent by weight and the rate of evaporation of water was routinely monitored by frequent weighing. The treatment in atmospheric conditions was extended over several days after which the solubility of the resulting films was determined. We observed that films which were treated as outlined here were completely soluble even when the atmospheric treatment at  $65^\circ$  C was extended over 37 days (compare entries 1-4 in Table 1). Another set of control samples was treated in the atmospheric oven at  $65^\circ \pm 0.5^\circ$  C for 6 days; films were then transferred to a vacuum oven and were treated under  $10^{-3}$  mm mercury over such time intervals and at such temperatures as were found necessary to bring about distinct impairment of their solubility. It was observed that increasingly higher temperatures and longer residence times under vacuum made gelatine films progressively less soluble (compare entries 5-10 in Table 1).

It seems certain that the insolubility of gelatine following sufficiently prolonged evacuation is a consequence of the formation of a three-dimensional network resulting from interchain cross-linking. Such cross-linking cannot be the result of an initial oxidative reaction, because prolonged exposure to the atmosphere does not itself diminish the solubility of gelatine (Table 1). Neither, apparently, is this cross-linking reaction necessarily caused by pyrolytic decomposition which gelatine might undergo at temperatures exceeding  $65^\circ$  C; we have, in

fact, found that gelatine films can be made partially insoluble if evacuated under  $10^{-3}$  mm mercury at temperatures as low as  $25^\circ$  C over a period of 40-50 days. We believe instead that the cross-linking of gelatine is a direct consequence of the removal of water below a critical trace level which we estimate to be 0.1-0.3 g water/100 g gelatine.

The proposed mechanism of insolubilization of gelatine in terms of a critical level of trace moisture below which cross-linking occurs serves to explain several observations which have been previously made in a number of laboratories. In these reports<sup>9,10</sup>, the occasional insolubility of gelatine samples, derived from a wide spectrum of mammalian sources, which were subjected to a variety of heat treatments and drying procedures was attributed to a number of causes, but the effect of trace moisture was apparently not directly investigated.

The chemical nature of the cross-links can perhaps be inferred directly from the work of Bello and Riese-Bello<sup>10</sup> on the solubility of certain chemically modified gelatines. These workers observed that gelatine which had been modified either by esterification of the carboxyl groups or by acetylation of the amino groups remained soluble in water even after being heated at  $108^\circ$  C for three days; by contrast, gelatine which was not so modified became insoluble under identical treatment. These and other results guided these authors<sup>10</sup> to the conclusion that gelatine becomes insoluble exclusively by formation of interchain amide links; the role of trace moisture was, however, not considered explicitly<sup>10</sup>.

Our proposal that the cross-linking of gelatine is a specific consequence of excessive dehydration is consistent with the detailed, independent observations referred to briefly here<sup>9,10</sup>. Drastic removal of the aqueous product of an amide condensation reaction can cause the equilibrium concentrations to shift irreversibly towards the right (formation of interchain peptide links). W. Kauzmann has suggested to us that mass action considerations alone can therefore account for the cross-linking of gelatine by dehydration.

Several proteins are known to contain carboxyl, amino and hydroxyl groups which could potentially condense either by esterification or by amide formation. It should be noted here that such reactions occur relatively slowly at moderate temperatures in the absence of a catalyst. Despite these considerations, we suggest that future investigations of proteins in the highly anhydrous state may very well reveal the occurrence of such irreversible transformations.

This work was performed at Princeton University and was supported in part by a US Public Health Service fellowship and in part by the Office of Naval Research.

## Chlorophyll - Water Interactions in the Solid State

A MARKED, reversible effect of water on the absorption spectrum of crystalline chlorophyll *a* in 'Nujol' mull has recently been observed<sup>1</sup>. Thin films of such mulls, dried by prolonged evacuation or standing over phosphorus pentoxide, absorb at 672 nm, but this absorption shifts to about 743 nm when the film is exposed to water, or if the chlorophyll contains water of crystallization. The infrared spectra of the wet and dry films are correspondingly different<sup>1</sup>. The 743 form shows only a single carbonyl absorption at 1,647  $\text{cm}^{-1}$ , similar to the band assigned to an "associated" carbonyl at the C(9) position in dissolved chlorophyll<sup>2</sup>, while the 672 species exhibits an additional infra-red peak at 1,698  $\text{cm}^{-1}$ , which has been assigned to a "free" carbonyl. The intensity of this band is about two-thirds that of the 1,647  $\text{cm}^{-1}$  peak. This suggests<sup>2</sup> that the 672 form contains dimers or other stoichiometrically associated forms. The differences in spectrum (both red and Soret bands) between the 672 species and the chlorophyll *a* dimer definitely identified in solution<sup>3</sup> may be attributable to effects of the medium or to exciton interactions in the solid phase. It is remarkable, however, that dimers in non-polar solvents are disaggregated by addition of small concentrations of Lewis bases (ethanol, pyridine, water)<sup>2,4</sup>, whereas in these chlorophyll crystal mulls, moisture increases the extent of dye interaction, as indicated by the bathochromic shift of the optical spectrum and, presumably, by the disappearance of the "free" carbonyl band. The water effect in solid chlorophyll has therefore been studied further, particularly to determine whether the 672-743 transition is sharp or whether intermediate forms can be obtained. Such intermediate forms are reported here.

Chlorophyll *a*, prepared from fresh spinach<sup>5</sup>, was brought into crystalline form by evaporation from solution in an ether layer on water. The material consisted of brilliant, purple microcrystals, and gave very sharp X-ray patterns agreeing with those of Donnay<sup>6</sup>. 'Nujol' mulls, spread evenly in thin films on 'Pyrex' plates, were equilibrated in absorption cells at various vapour pressures of water, controlled by connexion to water reservoirs which were maintained at temperatures lower than the films. The cell-reservoir assembly could be evacuated on the vacuum line and the cells closed off and removed for determination of the spectrum.

The position of the main red absorption band is found to depend on the water vapour pressure, the temperature of the film and equilibration time. The conditions in the previous work, in which the film was placed over water in a closed desiccator, were such that liquid water condensed on the film surface, thereby completely shifting the absorption from 672 to 743 nm. With more careful control of

Fig. 2. Visible spectra of films of chlorophyll *a* suspended in paraffin oil: —, film dried by evacuation for 2 h; ----, film exposed to vapour pressure of 15.5 mm for 4 h, at 27° C; ····, film exposed to vapour pressure of 15.5 mm for total of 26 h, at 27° C; — · —, film exposed to vapour pressure of 15.5 mm for total of 50 h, at 27° C.

hydration of the dry film, new absorption peaks have been observed at 716 and 733 nm (Figs. 1 and 2). In other experiments in which diffusion was much slower, peaks at 722 and 736 nm have been found. While the complicated vapour pressure, temperature and time dependence of the spectral shift have not yet been fully established, it is evident that a continuous shift in the visible spectrum between the extreme limits of 672 (dry) and 743 (wet) may be obtained. The spectrum can always be reversed back to 672 nm, from any stage of hydration, by drying on the vacuum line, or over phosphorus pentoxide.

The spectrum of the water-saturated 743 form of chlorophyll *a* is practically identical with the limiting spectrum of ethyl chlorophyllide *a* microcrystals of increasing size, prepared by dilution of acetone solutions with water<sup>7</sup>. The correlation between the magnitude of the spectral shift and the size of the chlorophyllide microcrystals<sup>8</sup> suggests that, in the chlorophyll-'Nujol' mulls, hydration controls the spectral shift (Figs. 1 and 2) in the same way, by controlling the size of the aggregate in which effective intermolecular dye interactions can occur, or by influencing the degree of coupling between the dye molecules. Either effect could result from a "tightening" of the crystal structure by added water. The mechanism may resemble the large red-shift in chlorophyll *a* "monolayers", produced by the presence of calcium ions<sup>9</sup>. The involvement of water in the crystallization of chlorophyll has also been noted earlier<sup>5</sup>. The manner in which hydration leads to disappearance of the "free" carbonyl absorption is still not clear.

## BIOLOGY

### Ultrasound in Adult Rodents

PRODUCTION of ultrasound by baby rodents has been reported by Zippelius and Schleidt<sup>1</sup> in *Apodemus f. flavicollis* Melchior, *Mus musculus domesticus* Ratty, and *Microtus a. arvalis* Pallas, and by Noirot<sup>2,3</sup> in baby mice, *Clethrionomys glareolus* Schr., *Mesocricetus auratus* Waterhouse and albino rats. I have now confirmed this phenomenon for the young of *Clethrionomys*, *Mesocricetus* and laboratory rats and mice, and extended it to the young of *Acomys cahirinus* (Desmarest), *Meriones shawi* Rozet, *M. unguiculatus* Milne-Edwards, a species of *Gerbillus*, *Apodemus sylvaticus* (L.), *Mus minutoides* and a species of *Thamnomys*.

In earlier reports ultrasound emission in the species studied ceased on the day on which the eyes opened. I have found, however, that in *Mesocricetus*, *Acomys*, *M. shawi* and laboratory rats ultrasound can be elicited, by handling, after the eyes of the young have opened. In laboratory rats, emission of ultrasound has been followed well into adult life. A continuation of juvenile behaviour due to daily handling can be eliminated, because out of ninety-one adult rats taken at random from normal departmental stock, forty-eight (approx. 53 per cent) produced ultrasound.

Ultrasound was monitored visually on an oscilloscope using a capacitance microphone and wide-band amplifier, and, at the same time, audibly by a "bat detector" as described by Pye and Flinn<sup>4</sup>. Samples of the pulses were recorded directly on magnetic tape. Two distinct types of pulse were produced by these adult rats: "short pulses", of length 30–60 msec at a frequency of about 50 kc/s, were produced by thirty-eight animals when handled; "long pulses" lasting up to 700 msec at about 22 kc/s were produced by twelve animals without handling. Two animals gave both types of pulse.

To elicit short pulses from older rats, they were rolled on their backs and restrained in positions resembling the full submissive posture of rats as described by Grant and MacKintosh<sup>5</sup>. This suggested that ultrasound might be associated with aggressive or submissive responses. To test this, one male rat, previously isolated for 10 days, was introduced into the cage of another, and the actions and postures of the animals, together with the types of pulse produced, were noted for 1 h. Forty different introductions were studied in this way; attacking and fighting occurred in many cases.

Short pulses were heard in every case except one. Long pulses were heard in twenty-six cases and could always be correlated with the long exhalations often shown by the submissive rat. Such abnormal respiration is probably that referred to by Seward<sup>6</sup>. Although the long pulses were initially associated with a submissive or crouch posture<sup>6,7</sup> they were sometimes heard later when the same animal was feeding or cleaning. In only three introductions were long pulses followed by any sort of conflict, actual fighting or boxing. It was difficult to see which animal was producing the short pulses, although sometimes they were synchronous with the head shaking of the aggressive rat as it left the submissive one after typical aggressive postures. Short pulses were often heard during all phases of aggressive behaviour, including fighting, except when the animals were in full aggressive-submissive posture or when one animal was grooming the other. These short pulses were also detected while activities such as feeding, cleaning and sniffing the cage (often occurring as obvious displacement activities) were performed.

In similar conditions of introduction, long and short pulses were detected from male rats (*Rattus norvegicus*) which had been trapped in the wild. No attacking or fighting was seen and in three out of seven introductions both animals remained "frozen" and silent for the whole hour. Short pulses, heard in two other cases, were associ-

ated with one animal approaching and sniffing the other. Long pulses, heard in four cases, were always associated initially with a submissive or crouch posture. One rat produced long pulses for 30 min after the other had been removed.

Many short pulses were detected when male rats were introduced into the cages of lactating or pregnant females, which are noted for increased aggressiveness. In one case these pulses could definitely be associated with the lactating female, for they continued after both her litter and the male had been removed, and were repeatedly obtained by disturbances up to 25 min later.

Short pulses at 50 kc/s were also detected when wild and laboratory males attempted to mount laboratory females or other males. Similar signals were found during intraspecific fighting between adults in *M. shawi*, a species of *Gerbillus* and a species of *Thamnomys* and from a disturbed lactating female *M. unguiculatus* while she thumped one hind foot on the ground. Pulses at 70 kc/s have been heard from mice of Noirot's impure strain, during attempted mounting and sniffing of either sex by males.

These observations suggest that ultrasound plays an important part in the social life of these adult rodents. So far the short pulses seem to be aggressive and the long pulses submissive. Certain aspects of this work including analyses of the ultrasounds and correlation with particular behaviour patterns will be reported in more detail later.

I thank Professor D. R. Arthur and Dr J. D. Pye for their help, and Mr J. Greaves, Ministry of Agriculture, Tolworth, for supplying the wild rats. This work was carried out with the aid of a Layton Science Research Studentship at King's College and a Science Research Council studentship.

### Circadian Periodicity of Blood Amino-acids in Adult Men

THE term circadian was introduced by Halberg<sup>1</sup> to describe a recurring sequence of events with a cycle of approximately 24 h, and the present knowledge of human circadian rhythms has been reviewed recently by Mills<sup>2</sup>. The circadian periodicity of a large number of constituents of blood, plasma, and urine has been described. Although a diurnal periodicity of whole blood amino-acids in man, in which concentrations at 2000 h were consistently greater than those at 0800 h on the same day, has been noted in this laboratory<sup>3</sup>, there were insufficient sampling times to establish a circadian pattern. A circadian periodicity of serum amino-acids in growing chickens<sup>4</sup> and whole blood tryptophan in mice<sup>5</sup> has been reported. We report here a circadian periodicity of whole blood and serum amino-acids in healthy adults.

Six healthy male volunteers, aged 20–23 yr, were placed in a hospital ward and subjected to uniform conditions of diet and activity. The subjects were informed of the nature and details of the investigations before they volunteered. Each subject was determined to be in excellent health by a check of his medical history, by a physical examination and by baseline laboratory determinations. Venous blood samples were collected at intervals of 4 h beginning at 0800 h on the day of admission and continued for 5 consecutive days. Amino-acids in 0.006 ml. of whole

Fig. 1. The total integrated value of amino-acids/0.006 ml. of whole blood averaged for men and days, plotted against hours of the day. Each point on the line represents the mean of thirty determinations. The mean value for each man at each point in time is indicated by the subject's number.

Fig. 2. Total serum amino-acids in mg per cent of a glycine nitrogen standard plotted against hours of the day. Each point on the line represents the mean of thirty determinations. The mean value for each man at each point in time is indicated by the subject's number.

blood were determined by the method of Efron *et al.*<sup>6</sup> and quantitated by densitometry. The sum of the integrated values for each whole blood amino-acid detectable as single spot (cystine, glutamine,  $\alpha$ -amino butyric, alanine and tyrosine) as well as those obtained for amino-acid groups (leucine and isoleucine; valine, methionine and tryptophan; glutamic acid and threonine; glycine, aspartic and serine; and lysine, arginine and histidine) was called the total integrated value. The error of the method as calculated from three standard deviations of the mean total integrated value of twenty replicate determinations of the same blood sample on the same day was 2.1 per cent. The error of the method calculated similarly from replicate determinations of the same blood samples on 20 different days was 5.7 per cent. Amino-acids which react with ninhydrin were determined on serum obtained at the same times of sampling according to the method of Moore and Stein<sup>7</sup>, with modification for the autoanalyser and the total value expressed as mg/100 ml. as compared with a glycine standard. The mathematical analysis of all data was conducted by Drs G. L. Jessup, L. W. Gaudette and W. D. Foster of the Biomathematics Division of Fort Detrick, using a 'Univac' solid state II computer.

Fig. 1 illustrates results obtained when the total integrated value in 0.006 ml. of whole blood is averaged for subjects and days with each point representing thirty determinations. The mean value for each man at each point in time is indicated by the subject's number. Fig. 2 presents a similar plot of results obtained from

autoanalyser analysis of serum. The periodicity observed by each method was characterized by the occurrence of maximal concentrations between 1200 and 2000 h and by minimum concentrations at 0400 h. The difference between results obtained at 0400 and either 1200, 1600 or 2000 h was statistically significant at less than 0.01. Similarly, the difference between concentrations at 1200, 1600 and 2000 h was not statistically significant with either analytical method. Figs. 3 and 4 illustrate results obtained when the mean concentrations of amino-acids of six subjects are plotted by the hour of the day for the 5 days of the experiment. The patterns seen on each day were similar.

Results plotted in Figs. 1 and 2 clearly show that the concentration of amino-acids in any single individual can be quite different from that obtained in any other individual although environment and diet are similar. Despite the differences in absolute concentrations, the periodicity patterns are alike. Results plotted in Figs. 3 and 4 demonstrate that the concentrations of amino-acids on any given day may be different from those obtained on any other day, but the rhythmicity observed is the same from day to day, that is, smallest and greatest concentrations occur at the same time each day. In addition, the individual amino-acids or groups of amino-acids listed here demonstrate the same periodicity as that illustrated for their sum.

Obvious differences exist between the large day-time values and the small night-time readings, but the reasons for these differences cannot be ascertained from these data or the experimental design employed. The hypothesis that a beta function or a Fourier series would represent

Fig. 3. Total integrated value of amino-acids/0.006 ml. of whole blood plotted against days of the observation period. Each point represents the mean value obtained for six subjects. Shaded areas indicate periods of sleep (2200-0600 h each day).

Fig. 4. Total serum amino-acids reported in mg per cent of a glycine nitrogen standard plotted against days of the observation period. Each point represents the mean value obtained for six subjects. Shaded areas indicate periods of sleep (2200-0600 h each day).

the data was not fully supported because of the tendency for values to form a plateau between 1200 and 2000 h.

There is a large range of reported values for plasma amino-acids<sup>8-14</sup>. We can find no information about sampling time in the literature detailing normal concentrations of amino-acids. Possibly the wide range of values reported is caused in part by differences in sampling time.

The influence of diet on concentrations of amino-acids in whole blood has been a source of considerable speculation. Rouser *et al.*<sup>15</sup> cite examples which demonstrate that dietary intake, provided it is in the form of food rather than a single amino-acid load, does not appreciably affect whole blood concentrations of amino-acids. Squibb<sup>16</sup> demonstrated that even in conditions of extreme protein deficiency in chicks, the free amino-acid pool remained at reasonably large levels and that large amounts of dietary protein did not result in an increase in this pool. In contrast, Frame<sup>17</sup> and others<sup>18</sup> reported that most amino-acids increase in concentration after a heavy protein meal, but there is no indication of the time of feeding and none includes control non-fed subjects who were sampled simultaneously. Frame<sup>17</sup> noted that the concentration of some amino-acids was higher 8 h after the test meal than in the fasting state. Although a large protein load may temporarily increase blood amino-acid concentrations, such a persistent 8 h increase may reflect an overall increase related to circadian periodicity rather than food intake.

The influence of exogenous rhythm synchronizers, for example, sleep and wakefulness, light and darkness, exercise, and the quality, quantity and time of food ingestion, must be considered. We are now trying to elucidate the contribution of each of these factors to the observed rhythmicity. In addition, the precise role of numerous individual hormones and other regulatory mechanisms in maintaining normal amino-acid periodicity remains undefined.

### Morphological and Physiological Distinction between Two Populations of the Peach-Potato Aphid

INDIVIDUAL *Myzus persicae* (Sulz.) which had survived repeated spraying with organophosphorus insecticides were collected from plants grown in glasshouses in 1963

and 1964 and were allowed to multiply on *Brassica pekinensis* Rupr. Several populations, derived from aphids collected in different glasshouses and from different species of host plant, were reared on *B. pekinensis* in separate insect proof cages for more than 2 yr. Experiments showed that these populations were much more resistant to organophosphates than another designated NC (normal colony), which had not been exposed to these insecticides<sup>1</sup>. During 1965 and 1966 experiments were carried out to investigate whether aphids from one of these populations resistant to insecticides (*RR3*) differed from NC aphids in morphology as well as in physiology.

Microscopic examination of individual adult apterae from the two populations showed that the longest ventral hairs on the hind femur of *RR3* aphids were usually shorter than those of NC aphids (Figs. 1 and 2). The difference between the mean hair lengths of the two populations was  $3.8\mu \pm 0.36$  ( $P < 0.001$ ), indicating that the length of femoral hairs was a good criterion for distinguishing between them. To test the reliability of this distinction, a random sample of adult, apterous *RR3* or NC aphids was placed in a series of tubes which were identified only by code numbers. Every sample was identified correctly by comparing the mean lengths of the femoral hairs of aphids in the different tubes.

There was some correlation between the length of the femur and the length of the femoral hairs in the apterae of the NC aphids, but in the alatae of both samples and the apterae of *RR3* there was little increase in hair length with femur length. Small apterae (antennal segment III 300–375 $\mu$  long) of *RR3* aphids usually had the hind femur 1.3–1.4 times as long as antennal III, while similar sized NC apterae usually had the ratio 1.4–1.5. Large apterae (antennal III 425–525 $\mu$  long) of both populations had the hind femora 1.35–1.55 times as long as antennal III.

The experiments demonstrated that apterae of the *RR3* and NC clones could be distinguished by comparing their resistance to insecticides and also by comparing the length of femoral hairs. It would be necessary to examine the femoral hairs of other populations resistant to insecticides to establish whether there is a genetic linkage between resistance to organophosphates and short femoral hairs. Linkages between genes, which control specific

Fig. 1. Anterior surface of middle third of hind femora of *Myzus persicae*; A, population NC; B, population *RR3*.

Fig. 2. Distribution of femoral hair lengths from NC and RR3 populations.

morphological and physiological characters, would be particularly useful in identifying individual aphid populations. *M. persicae* consists of a vast complex of clones which differ morphologically and physiologically<sup>2</sup>, and the taxonomy of populations such as RR3 presents special difficulties.

Systematic relationships are usually based on studies of a wide range of inter-related morphological characters; tests of interfertility are rarely used because of practical difficulties. Morphological characters can always be checked on preserved specimens and a system of nomenclature, based on type specimens, can conveniently be used. Aphid populations, however, which have genes of economic importance in common, are often considered to be of the same strain or race, although they may differ from one another in many morphological and physiological characters. Resistance-breaking populations of *Amphorophora rubi* (Kalt.) on raspberry are examples of such strains<sup>3</sup>. Resistance to insecticides, or the ability to overcome the resistance of host-plant varieties, is unlikely to be permanent in aphids, particularly in those species with wide host ranges. There is therefore little point in applying a formal system of nomenclature to populations such as RR3, although it is convenient to apply the terms "strain", "race" or "biotype" to them. It must, however, be emphasized that these terms do not imply that strains are homogeneous except for certain specific characters.

## Energy Flow in *Euphausia pacifica*

To understand relationships within food webs in the sea, with an eye to predicting and perhaps ultimately improving the efficiency of the production of commercially important species, we must understand the energetics of the lower elements of the food web. Energy flow more accurately represents the significance of a species in a community than either the numbers or the biomass of the species<sup>1</sup>. Euphausiids (class Crustacea) are pelagic filter-feeders of world-wide distribution which serve as forage for a wide variety of marine animals, including whales<sup>2</sup> and salmon<sup>3</sup>. *Euphausia pacifica* Hansen, the principal species in the North Pacific, often represents the largest biomass of the macroplankton in the subarctic and transitional water masses<sup>4</sup>. The species is a vertical migrant, inhabiting depths of roughly 100–500 m during the day and ascending to surface waters at night<sup>4</sup>. It is exposed to water temperatures of about 5°–15° C off Oregon (depending upon season and depth of migration); 10° C is the approximate average<sup>5</sup>. Day length varies off Oregon from about 8 h in winter to 16 h in summer, so that the time spent in waters of different temperature varies seasonally<sup>6</sup>.

Enough is now understood about the metabolic requirements of *E. pacifica* in different environmental conditions to make possible a reasonably accurate assessment of annual energy flow in this species off Oregon, and some prediction of energy flow throughout its range in the North Pacific. Energy flow was calculated from the equation assimilation = respiration + growth, where assimilation is approximately equivalent to energy flow<sup>7</sup>. The calculations were first expressed as g cal / "average" animal / day on a monthly basis. To estimate the "average" animal weight each month, the percentage contributions of small, medium-sized, and large animals were computed on a monthly basis (Table 1). The weight-frequency distribution of animals in the area of collection was roughly bimodal from spring to early summer. One mode ranged from 0.3–1.8 mg dry weight (mean, 0.9 mg), and the second mode from about 6.1–15.5 mg (mean, 8.2 mg). The dry weight range of intermediate sized euphausiids was 1.9–6.0 mg, with a mean of 4.3 mg. The adjusted monthly mean weight of the population was estimated by multiplying the mean weight of each size group by its percentage occurrence in the population for the specified month, then summing the three products and dividing by 100.

Table 1. PERCENTAGE OF SMALL, MEDIUM-SIZED, AND LARGE *E. pacifica* IN THE POPULATION EACH MONTH

Month	Per cent of total population		
	Small	Medium	Large
January	96%	4%	0%
February	86	14	0
March	76	11	13
April	70	9	21
May	65	8	27
June	61	7	32
July	95	3	2
August	89	8	3
September	87	10	3
October	84	13	3
November	98	2	0
December	97	3	0

Small animals ranged from 0.3–1.8 mg dry weight (mean 0.9), medium-sized animals from 1.9–6.0 mg (mean 4.3), and large animals from 6.1–15.5 mg (mean 8.2).

Measurements of respiratory rates were made in a Gilson differential respirometer<sup>8</sup> at 5°, 10°, and 15° C, after the animals had been collected at sea with either 0.5 or 1 m nets (mesh size 0.239 mm). A mean respiratory rate for each temperature was calculated, in  $\mu$ l. of oxygen/mg of dry weight/h. The approximate daily rate of respiration of the population in any one month was obtained by first computing  $\mu$ l. of oxygen/mg consumed during that portion of the day spent in surface waters, then computing  $\mu$ l. of oxygen/mg consumed during the remainder of the day at maximum depth, and then summing the two estimates to yield  $\mu$ l. of oxygen/mg/day. Daily respiration

was converted to g cal/"average" animal/day by first multiplying by an oxy-caloric coefficient of 0.005 g cal/μl. of oxygen (ref. 9), and then by the mean weight of the population.

Growth rates were estimated from weight-frequency data on natural populations collected by trawling off the Oregon coast. There was no significant difference ( $P=0.05$ ) among the mean seasonal rates, or between growth rates of small (young) and large (adult) euphausiids. The overall mean rate of growth was used as the best estimate of euphausiid growth (0.0104 mg of dry weight/day). This overall mean rate agreed well with rates determined for euphausiids maintained at 10° C in the laboratory<sup>10</sup>. Conversions of daily growth rate to growth estimates in g cal/"average" animal/day for each month was accomplished as follows. Weight-specific calorific values of the three size groups of *E. pacifica* were determined in a Parr adiabatic bomb calorimeter (Table 2). On a dry weight basis the values varied by size group, a phenomenon noted also in *Daphnia pulex*<sup>9</sup>. Each increment in the growth attained of a large animal represented therefore a greater caloric addition than the same increment of growth in a small animal. Clearly, growth in the population, when expressed in calories, was a function of size structure of the population. To obtain g cal/"average" animal/day it was necessary to multiply the growth rate of each size group (in g cal) by the respective percentage contribution of each group to the total population, sum the products, and divide by 100.

Table 2. CALORIFIC VALUE OF SMALL, MEDIUM-SIZED, AND LARGE *E. pacifica*, IN G CAL/MG DRY WEIGHT

Determination	Small	Medium	Large
1	4.452	4.694	5.411
2	4.080	4.622	4.893
3	4.206	4.408	5.339
4	4.517	4.165	5.505
5	4.353	4.535	4.962
6	3.998	4.854	5.173
7	4.321	4.623	5.036
8		4.244	4.984
9		4.495	
10		4.780	
11		4.371	
Mean	4.275	4.526	5.163
Standard deviation	0.190	0.216	0.230
Coefficient of variation	4.44%	4.77%	4.45%

Weight ranges of size groups are as given in Table 1.

Respiration and growth, in g cal/"average" animal/day, were summed to estimate energy flow (Fig. 1). The increase in energy/"average" animal from January to early June was largely the result of an increase in weight of the "average" animal during this time. Spawning occurs mainly in June<sup>11</sup>, so the mean weight/animal, and thus

energy flow/"average" animal, decreased significantly after this month because of the appearance of many young animals in the population. A smaller decrease occurred after October, but this was because larger animals dropped out of the population in the collecting area rather than because young animals entered the area.

Because of the patchy distribution of euphausiids, the variation in total numbers/unit volume of water was great; thus energy flow/unit volume was not computed. If, however, energy/"average" animal for each month is divided by the mean weight for each month, g cal/mg/day can be plotted (Fig. 1). This curve can be considered indicative of the effects on respiration of changing environmental conditions (particularly temperature and photoperiod). A comparison of the two curves in Fig. 1 shows that size structure of the population has more influence on annual energy flow than temperature and photoperiod. The annual ranges of temperature and photoperiod off Oregon are reasonably representative for the whole oceanic region inhabited by *E. pacifica*, particularly when vertical migration is taken into account. The applicability of the energy flow estimates off Oregon to the rest of the North Pacific, however, depends almost entirely on whether changes in size structure of the population off Oregon are representative. This, of course, is not known, but Ponomareva's<sup>11</sup> account of the life cycle of euphausiids in the eastern North Pacific indicates that it may be so.

Integration of the area under the curve for g cal/"average" animal yielded an annual energy flow of approximately 100 g cal/"average" animal. The weight-specific value was slightly less than 60 g cal/mg dry weight/yr. Lasker<sup>10</sup> found that the assimilation of ingested carbon by *E. pacifica* was on average 84 per cent in animals maintained in the laboratory. If this figure generally holds for animals in the natural environment, the "average" animal ingests roughly 15 mg of carbon/yr, using the conversion of 8 g cal/mg of carbon and assuming complete biological oxidation of all assimilated carbon. On a weight-specific basis, ingestion is about 9 mg of carbon/mg dry weight/yr.

This work was supported by grants from the US Public Health Service and Atomic Energy Commission. I thank Dr William Pearcy for use of his data on seasonal euphausiid abundance off Oregon.

## Newt Orientation by Sun-compass

SALAMANDERS migrate long distances to breeding sites<sup>1</sup>, and apparently possess an accurate guidance mechanism<sup>2,3</sup>. The homing of blinded *Taricha* after being displaced downstream suggests that they rely on olfactory cues<sup>4</sup>. The ability of the normal animal to use vision in orientation, however, has received little attention. Three species of frogs and toads use a sun-compass<sup>5-7</sup>, and the toad, *Bufo woodhousei fowleri*, can learn a direction of escape relative to a light cue<sup>8</sup>.

We have trained newts and tested them in a circular arena (4 ft. diameter with 1.33 ft. high wall) with eight covered goal boxes attached at equal distances around the outside. The boxes opened into the arena through doors (4 in. by 4 in.) located at 45° intervals around the circular wall. The arena was surrounded by a wall of white curtains (10 ft. diameter). A 175 W sun lamp, situated at an angle of 51° above the base of the arena, provided the only asymmetry within the test area as viewed from the centre of the arena. Newts were trained under the sun lamp to move in a particular direction from the centre of the arena to an open goal box. During training, the angle between the open goal box and the light was the same, and a moist sponge (4 in. long, 3 in. wide, 1 in. thick) and pieces of earthworm were placed in the box as a reward.

The first group (A) of twelve newts was trained to find a goal box located 90° to the right of the sun lamp (directions expressed from the centre of the arena). These animals were given ten conditioning trials (1 h trial/day) with the same box (No. 0) open each day. After several training sessions, newts moved rapidly to the box and spent the remainder of the hour inside. They were tested with all the boxes open, the arena in the training position, but without a sponge or earthworms. In two tests, these newts preferred box No. 0 which was 90° to the right of the light (Fig. 1a). Scores were recorded when an animal entered a box. All data were analysed for randomness by the Rayleigh test ( $P = 0.05$ ) and the mean angles of scores shown in the figures were computed vectorially<sup>9</sup>.

Immediately after the previous test the part played by odour was investigated with a second group (B) of twelve newts. These newts were untrained and had never been in the arena. When released with the arena in the same position, eight newts moved to Box No. 0, where eleven newts had scored in the preceding tests (Fig. 1b). These untrained animals did not appear to follow scent trails, and explored the arena before entering a goal box.

Fig. 1. Directional responses of newts trained to an escape direction relative to a sun lamp. (a) The arena in the training position; (b) untrained animals released immediately after the previous test; (c) familiar boxes (No. 0 and No. 4) rotated 90°; (d) familiar odours in each box; and (e) light moved 180° from the training position. The null hypothesis of random distribution was rejected for all tests.

Fig. 2. Responses of newts to visual cues with odours minimized. (a) Test of trained animals with indirect illumination in place of a light cue; (b) light cue in training position. Tests with the light cue (c) in the training position and (d) moved 180°. Response of newts trained under a sun lamp and tested under (e) an infra-red lamp; (f) a red flood lamp moved 180°. The null hypothesis of randomness is accepted for scores in Fig. 2a and take-off directions in Figs. 2a and 2f; all others are rejected.

Group B was trained to enter a box 90° to the right of the light and was used in a test comparing visual and olfactory cues. Training was similar to that used earlier, except that boxes No. 0 and No. 4 were open on alternate days. After the arena was rotated to bring box No. 6 in the trained direction, these newts were tested three times and both the directions of take-off and the boxes they entered were recorded. The animal's position halfway to the arena wall constituted the direction of take-off. In these tests thirty-three newts scored in boxes No. 0 and No. 4, but the take-off directions were toward box No. 6 (Fig. 1c). If odours were detected from the centre of the arena, the take-off direction should have been toward the box entered.

The arena was cleaned thoroughly and repainted. Four sponges were placed in the aquarium holding group A for 48 h and four sponges were similarly placed with group B. These sponges should have provided "home" scents. Sponges from aquarium A were alternated in the goal boxes with those from aquarium B and newts (A and B) were tested twice. The scores and directions of take-off were to the right of the light and usually in the trained direction (Fig. 1d). The sponges did not appear to influence the choice of boxes.

To test the use of potential cues other than the light (for example, sound, kinaesthetic information, odours), nine newts, group C, were trained to locate a box 90° left of the light source. These animals were tested twice with the light moved 180°. Box No. 2 was in the trained direction (No. 0 and No. 4 used for conditioning) and sponges were placed in the goal boxes as described previously. Of the eighteen scores, fifteen were within 45° of the trained direction relative to the rotated light (Fig. 1e).

Groups *A* and *B* were conditioned twice to Box No. 4 and were tested on the third day with box No. 1 rotated to the trained direction (90° right of the light). The arena and boxes were painted daily, and before each test a new sponge, moistened in tap water, was placed in each box. During tests, the sun lamp was placed underneath the arena, where it illuminated the curtained area evenly but was not visible to the test animals. The scores and directions of take-off were scattered in these tests (Fig. 2a). When the sun lamp was placed in the original training position, these newts again favoured the direction which they had been trained to take (Fig. 2b).

Other tests have verified that *T. granulosa* uses light cues. Group *D* was trained to locate a box 90° to the right of the sun lamp and was tested four times with the light in the training position. The entire arena was painted before all group *D* tests and fresh sponges placed in each box. Most newts scored to the right of the light (Fig. 2c). After the light was moved 180°, seventeen of forty-eight newts moved in the trained direction relative to the new cue position (Fig. 2d). Take-off directions corresponded to the new light position.

The sun lamp was moved to the original training position and group *D* was conditioned six times. An infra-red lamp (250 W) was substituted for the sun lamp. When these newts were re-tested, twenty-four of forty-eight scores were within 45° of the trained direction (Fig. 2e). The infra-red lamp emitted less light but more heat. Take-off directions were more scattered than under the sun lamp. Next, a red flood lamp (150 W) was used and the light source moved 180°. In these tests, thirty-four of forty-eight scores were within 45° of the trained direction, but take-off directions were scattered (Fig. 2f). These newts were slow to score and seemed less responsive to the low light and heat intensities of this bulb.

*T. granulosa* uses information from light cues in its orientation and has a very well developed olfactory sense. Our findings and those of Twitty and his associates<sup>10</sup> suggest that further investigation could show the relative value of these two orientational mechanisms in the natural environment.

### Behavioural Responses to Contact with DDT in *Anopheles atroparvus*

We have obtained two colonies of *Anopheles atroparvus* by selecting for escaping (colony *A*) and not escaping (colony *B*) from a tube lined with paper impregnated with DDT dissolved in 'Risella' oil<sup>1</sup>, and this selection has now reached the *F*<sub>32</sub> generation. Percentages of escapes, which differed widely in both males and females, have not changed significantly since the tenth generation. Neither DDT nor its solvent has been found to be essential for the escape reaction, but each greatly enhances the response.

In this communication we analyse some aspects of the behaviour underlying the escape flights. We started with a series of tests in which the length of the exposure tube and the diameter of the escape hole could be altered (Fig. 1). The results indicated that both the length of the tube and the diameter of the hole influence the percentage of the mosquitoes escaping but that there is no interaction between the effects of the two variables. We concluded therefore that the length of the tube and the diameter of the hole affect different components of escape behaviour. In each case more mosquitoes of colony *A* escaped than of colony *B*.

Fig. 1. Percentage of escapes of single 1 day old empty females of *Anopheles atroparvus* of colony *A* (○ ○ ○) and *B* (● ● ●) from tubes lined with filter-paper impregnated with 4 per cent DDT, put into different lengths and 40 mm in diameter, in relation to the diameter of the escape hole. Tests were run in complete darkness. Duration of tests was 1 min (preceded by 3 min of adaptation). Numbers used/point were for colony *A*, twenty-nine to forty-four; for colony *B*, thirty to fifty-eight. Tube lengths, ———, 12 cm; ---, 36 cm; ····, 60 cm.

The first component of escape behaviour which we investigated was flight within the tube. To record this a narrow slit along the length of the tube was left unlined, and with this part uppermost and a source of illumination placed below the tube we followed by hand, with a pencil on a paper moving at 22.5 cm/min, the movements of a single mosquito. In this way we obtained a 'kinetogram' for each mosquito tested. The two selected strains showed quite different flight patterns, two typical specimens of which are shown in Fig. 2. These patterns have been analysed for (a) activity expressed by the percentage of mosquitoes taking off at least once; (b) activity expressed by the number of take-offs/active mosquito; (c) activity expressed by the total time flown/active mosquito (a mosquito was considered to be flying as long as it was on the wing, part of the flying time being consumed by hovering and part by actual locomotion); (d) speed of flight; (e) number of turns/sec of 'productive flying-time', this being the time consumed by locomotion over a distance of at least 5 cm of tube length; and (f) number of turns/m covered. The results are shown in Table 1 and Figs. 2 and 3. They show that the mosquitoes of colony *A*

Table 1. DIFFERENT ASPECTS OF ACTIVITY OF SINGLE 1 DAY OLD EMPTY FEMALES OF *Anopheles atroparvus*, EXPOSED TO 4 PER CENT DDT

	Colony A	Colony B
Percentage of active mosquitoes	100.0 (25)	88.0 (25)
No. of take-offs/active mosquito	14.1 (25)	9.8 (22)
Time flown/active mosquito (sec)	107.8 (25)	63.7 (22)
Speed of flight (cm/sec)*	15.5 (25)	12.2 (20)
No. of turns/sec of "productive flying time"*	0.29 (25)	0.38 (22)
No. of turns/m flown*	1.87 (25)	3.13 (20)

The mosquitoes were exposed to the DDT in a tube 46 cm long. Activity was analysed by means of kinetograms. Experimental conditions were as described in the text. Duration of the tests was 3 min (preceded by 3 min of adaptation). Numbers of mosquitoes are in parentheses.

\* Determined during 3 min adaptation and 3 min test.

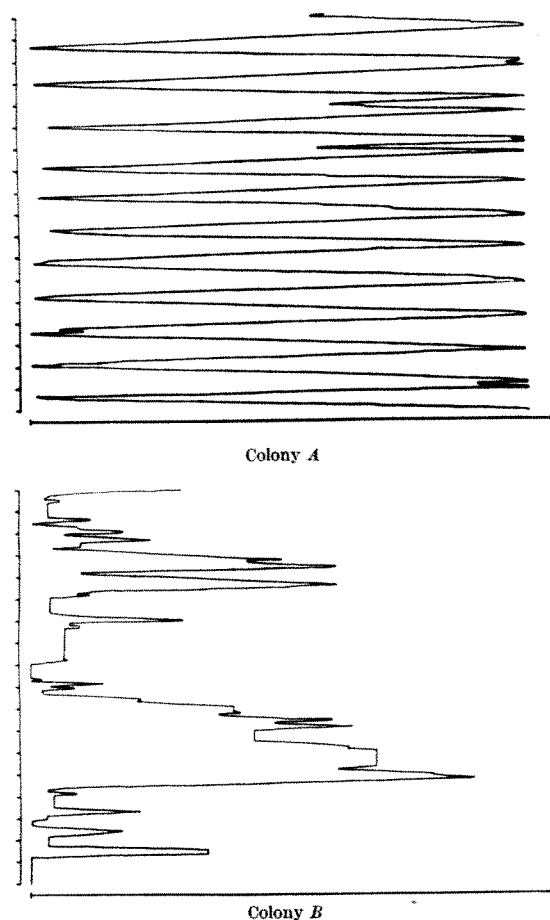

Fig. 2. Kinetograms of single females of *Anopheles atroparvus* of colony A and B, recorded in the conditions described in the text. Time is marked on the vertical scale with 5 sec intervals.

have a greater average speed of flight than those of colony B; there is even a sharply defined discriminating speed of flight, for only four mosquitoes of colony B flew faster than 14 cm/sec and only four mosquitoes of colony A were slower. The mosquitoes of colony A fly more directly from one end of the tube to the other. Those of colony B turn more frequently in each metre covered. Although there is apparently a negative correlation between the number of turns/m and the speed of flight, the former was excluded as a possible cause of the different speeds of flight of A and B mosquitoes. The average speed of flight in 100 long, straight flights recorded for B mosquitoes was found to be 12.8 cm/sec. This was exactly the same as the average speed of flight of B mosquitoes in flights with frequent turns. The activity, judged by the criteria (a)–(c), is greater in mosquitoes of colony A than in those of colony B.

The second component of escape behaviour which we investigated was flight in relation to the escape hole. In order to measure the capacity of a single mosquito for escaping, it should be given the opportunity of escaping repeatedly. This can be achieved when the mosquito, after escaping from the exposure chamber, finds exactly

Table 2. DIFFERENT ASPECTS OF ACTIVITY AND PERCENTAGES OF ESCAPING BY SINGLE 1 DAY OLD EMPTY FEMALES OF *Anopheles atroparvus*

	Colony A	Colony B
Percentage of active mosquitoes	98.0 (100)	94.0 (50)
No. of take-offs/active mosquito	11.2 (98)	8.2 (47)
Time flown/active mosquito (sec)	77.2 (98)	42.3 (47)
Percentage of active mosquitoes escaping	91.8 (98)	2.1 (47)

Activity was recorded in WHO irritability test funnel completed with its reflected image (bases covered with filter-paper impregnated with 4 per cent DDT in 'Risella' oil; diameter of escape hole, 11 mm).

Duration of the tests was 3 min (preceded by 3 min of adaptation). Numbers of mosquitoes are in parentheses.

the same conditions as before escaping. These conditions were met simply by using two World Health Organization irritability test funnels (slightly modified) joined together. The pair of funnels, top-holes combined so as to make one escape hole common to both sides, and their bases covered with DDT-impregnated paper, were illuminated from below. With this apparatus we made simultaneous observations of the number of escapes, the activity expressed by the number of take-offs and the activity expressed by the total time flown. The results are shown in Table 2 and Fig. 4.

This quantitative method of estimating escape reactions of single mosquitoes in short tests confirms that A and B mosquitoes differ in their capacity for escaping. The

Fig. 3. The relation between the speed of flight and the number of turns/m flown by a single 1 day old female of *Anopheles atroparvus* watched for 6 min. Experimental conditions were as described in the text. ○, Colony A; ●, colony B.

Fig. 4. The relation between activity (total time flown) and number of escapes of single 1 day old empty females of *Anopheles atroparvus*, exposed to 4 per cent DDT in two combined WHO irritability-test funnels. Experimental conditions were as described in the text. Duration of the tests was 3 min (preceded by 3 min of adaptation). ○, Colony A; ●, colony B.

activity is greater in mosquitoes of colony *A* than in those of colony *B*, although there are individual *B* mosquitoes which are very active. Although the number of escapes is related to the minimum activity, escaping is not a direct result of activity. Thus irritation by DDT accounts for increased activity, but the ability to escape is a separate component of behaviour.

### Morphological Changes in a Parasitic Nematode due to Acquired Resistance of the Host

THE vulval flap of trichostrongylid nematodes is of interest to taxonomists and its presence or absence and its form are regarded as characteristic of different species. Recent work with experimental infections of *Ostertagia ostertagi* in calves has shown that the vulval flap, which in this species is normally large and well developed, may be greatly reduced or entirely absent in worms from resistant hosts. This is illustrated in Fig. 1.

The burden of adult worms of calves exposed to constant infection with this parasite is regulated by a loss of worms and their replacement. The rate of loss depends on the number of worms present, with the result that the worm burden is maintained at the level at which the appropriate loss balances the acquisition of new worms. Thus there is a rapid turnover of worms and consequently the worms present at any moment have developed recently.

In an experiment in which three groups of calves were infected daily at different rates, it was found that the percentage incidence of female worms, in which the vulval flap was greatly reduced or absent, increased with the passage of time. The increase in incidence appeared to be linear and its rate positively related to the infection rate (see Fig. 2). A closer study of the results suggests that the percentage of flapless females is proportional to the host's experience of the presence of adult worms as measured by the product of the mean number of adult worms and the time for which they have been present. In further

Fig. 1. Vulval region of three mature female *Ostertagia ostertagi*. The worm on the right has a normal vulval flap, that on the left a greatly reduced flap. The worm in the middle has no vulval flap.

Fig. 2. The incidence of female *O. ostertagi* without vulval flaps in populations of worms from three groups of calves which received infective larvae daily at the rate of 500/day (●—●), 1,000/day (×---×) and 1,500/day (○...○) respectively.

experiments it was shown that the administration of cortisone to calves receiving infective larvae daily prevented an increase in the incidence of flapless females, even though a turnover of worms was taking place.

Other experiments showed that in calves infected on one occasion only, the percentage of flapless females in the resulting population was low and was not affected by the size of the infection. On the other hand, when a first infection established by the administration of a single dose of larvae was entirely removed by anthelmintic treatment and replaced by means of a similar single dose of larvae from the same culture, the incidence of flapless females was 7.3 per cent in the first infection and 26.9 per cent in the second. It was shown further that, as a population of worms of uniform age decreases in number, the percentage of flapless females remains unchanged.

These experiments were carried out with a strain of *O. ostertagi* grown from ova from females especially selected as having a well developed vulval flap. When larvae from this culture were administered to calves free from worms a small proportion of the resulting adult worms were without flaps and this incidence has not changed in successive passages through susceptible calves. It has been shown<sup>1</sup> that the worms present in calves exposed to constant infection with *O. ostertagi* become smaller with the passage of time. Within any population of worms from such calves the flapless worms are not merely the small worms. If anything, the flapless worms are longer, but this difference is sufficiently small to be explained by the fact that the different members of the population completed their development over a period of about a month.

The increasing incidence of flapless females in calves exposed to repeated infections cannot be attributed to the accumulation of members of a distinct variety of subspecies which is lost from the host more slowly than the more common form. Were this so, the size of flapless worms from such calves would be expected to decrease less rapidly than that of worms with vulval flaps. Furthermore, the percentage incidence of flapless females in populations, in which all the worms are of the same age, would be expected to increase as the number of worms decreases.

All the evidence suggests that conditions for the development of the vulval flap are less favourable in hosts that have had previous experience of infection and that the extent of this change in conditions may be proportional to the host's experience of the presence of adult worms. That immune mechanisms are involved in the deterioration of conditions is indicated by the effect of treating the host with cortisone. Thus the phenomenon of flaplessness resembles other phenomena of host resistance to infection with *O. ostertagi*. These also appear to be due to a deterioration in the environment which in turn is the consequence of immune reactions, and the extent

of the deterioration seems to be directly proportional to that of the cause by which it is elicited. In spite of this basic similarity, flaplessness and the various other manifestations of resistance can be shown to be distinct in their causation as well as in their effects.

### Inhibition of Respiration of *Chlorella vulgaris* by Simultaneous Application of Cupric and Fluoride Ions

IN experiments of short duration, the respiration of many micro-organisms is diminished only a little, if at all, by cyanide or by fluoride at concentrations which inhibit the main respiratory system of higher animals. I have used a strain of *Chlorella vulgaris* in which the respiration is insensitive to fluoride, cyanide and (in aerobic conditions) copper ions, but when suitable amounts of copper sulphate and sodium fluoride are added simultaneously to a cell suspension, oxygen uptake almost ceases. No similar effect has been seen when other metals are substituted for copper, or when most other anions are substituted for fluoride. Cyanide and iodide are exceptions, but both of these interact with cupric copper. The addition of citrate, to avoid possible precipitation of sparingly soluble basic copper fluoride, does not make copper sulphate or sodium fluoride more toxic when these are added to cells singly, nor does it reduce the inhibition of respiration which occurs when they are applied simultaneously (Fig. 1).

In mixtures containing less copper sulphate or sodium fluoride, the respiratory inhibition is less and apparently can disappear at appropriate concentrations. Nevertheless, interaction is still taking place, for cell suspensions treated with even smaller concentrations absorb considerably more oxygen than do untreated suspensions. The figures in Table 1 represent the respiration of standard cell suspensions expressed as percentages of the respiration of untreated controls, the data being based on the oxygen uptake for the 60 min period after addition of the poisons. The experiments were carried out in aerobic conditions

Table 1. RESPIRATION, AS A PERCENTAGE OF THAT OF UNTREATED CONTROLS, AFTER ADDING MIXTURES OF COPPER SULPHATE AND SODIUM FLUORIDE TO A SUSPENSION OF CELLS OF *Chlorella vulgaris*

Copper sulphate (moles/l.)	Sodium fluoride (moles/l.)		
	0	$8 \times 10^{-3}$	$4 \times 10^{-2}$
$6.6 \times 10^{-3}$	110	226	43
$1.3 \times 10^{-2}$	111	256	82
$4.0 \times 10^{-3}$	112	237	175
$2.5 \times 10^{-3}$	101	140	160
$3.1 \times 10^{-4}$	100	—	144
0	100	121	146

in a Warburg respirometer provided with a light-excluding canopy and at a temperature of 30° C.

Insensitivity of respiration to fluoride has often been attributed to the presence of a respiratory pathway which is not dependent on enolase. *Escherichia coli*<sup>1</sup>, *Pseudomonas aeruginosa*<sup>2</sup>, *Bacillus subtilis*<sup>3</sup> and *Chlorella pyrenoidosa*<sup>4</sup> are among organisms, strains of which have been demonstrated to be fluoride-insensitive, though the techniques used have sometimes measured gas exchange and sometimes substrate utilization. The alternative pathway has been characterized tentatively as the pentose phosphate system<sup>5,6</sup>.

Perhaps the most striking respiratory peculiarity of *Chlorella* when it is treated with a respiratory poison is its ability to switch from a main to an alternative pathway capable of assuming the full respiratory load; in contrast, tissues of higher organisms in similar circumstances respond by undergoing a reduction in respiration to a "cyanide-resistant" or "fluoride-resistant" level. If fluoride blocks a main pathway dependent on enolase, the foregoing observations suggest that (a) an alternative respiratory pathway is disturbed or inhibited by concentrations of copper ions exceeding approximately  $2 \times 10^{-4}$  molar, and (b) both respiratory pathways are blocked when the two poisons are applied together. I am investigating the possibility that the pentose phosphate system is the alternative copper-sensitive system.

## BIOCHEMISTRY

### Evidence for binding of Cytoplasmic Creatine Kinase to Structural Elements in Heart Muscle

THERE have been suggestions<sup>1,2</sup> that cytoplasmic creatine kinase is not always free in solution in the cell, but that it is in part bound to structural elements, for example myofibrils. Some evidence for this is provided *inter alia* by localization studies<sup>3-5</sup>. I have obtained direct evidence for the binding of some cytoplasmic creatine kinase by isolation and crystallization of the enzyme from the myofibrillar fraction of a heart muscle homogenate. The enzyme was differentiated from the mitochondrial creatine kinase, which forms about 50 per cent of the total creatine kinase activity in heart muscle<sup>6</sup>.

Beef heart (800 g) was homogenized in 4 l. of 0.25 mmolar sucrose, containing 20 mmolar triethanolamine buffer, pH 7.2, and 2 mmolar EDTA, according to the recommendations of Green and Ziegler<sup>7</sup>. The myofibrillar fraction was centrifuged down at 1,000g for 15 min and the supernatant, containing the mitochondria as well as the sap, was removed. The precipitate was suspended in

Fig. 1. Electrophoresis of creatine kinase preparations on acrylamide gel, pH 9, 2.5 h, 10 V/cm (cathode direction is indicated by +). A, Commercial creatine kinase; B, creatine kinase from myofibrillar fraction of ox heart; C, creatine kinase from ox heart mitochondria. The areas showing enzyme activity are shaded.

1 l. of sucrose medium, and rehomogenized in a Waring blender for 30 sec. The suspension was centrifuged for 20 min at 6,000*g* and the supernatant decanted off. This procedure was repeated five times. On each occasion the supernatant was tested for creatine kinase activity by the method of Bücher *et al.*<sup>8</sup>. After the fifth and sixth washes, the activity in the supernatant was negligible ( $< 0.1$   $\mu$ /ml. solution). (1  $\mu$  = 1  $\mu$ mole ATP disappearing/min, in the conditions of Bücher *et al.*<sup>8</sup>.) The gelatinous precipitate was then extracted by suspending in 1 l. of ice-cold 0.02 molar phosphate, pH 7.2, and standing overnight at 2° C. The precipitate was centrifuged off, and the creatine kinase activity of the supernatant was found to be about 2  $\mu$ /ml. and 5  $\mu$ /mg protein.

The enzyme was concentrated by precipitation with 2 mmolar ammonium sulphate at pH 7.8, and purified by fractional precipitation with acetone at pH 9. The fraction which precipitated between 35 and 45 per cent acetone was allowed to crystallize at pH 8.4 in a solution of very low ionic strength, as described by Jacobs, Klingenberg and Ottaway (in preparation). The activity of the crystals was about 18  $\mu$ /mg, and the yield was 8.6 mg.

Electrophoresis in acrylamide gel at pH 9 (0.04 molar glycine buffer, 0.01 molar sodium chloride, 0.01 molar creatine) showed that the preparation was not completely pure. The impurities were stained with naphthalene black and had electrophoretic mobilities very similar to those of impurities found in a commercial preparation of crystalline muscle creatine kinase (obtained from Boehringer and Söhne, Tutzing). All the enzyme activity detected on the gel by the method of Burger *et al.*<sup>9</sup> was found in a spot with slightly less mobility than that of the commercial sample. No trace of activity was found near the origin, where mitochondrial creatine kinase migrates in these conditions (Fig. 1).

A significant amount of creatine kinase, with electrophoretic properties similar to those of muscle (cytoplasmic) creatine kinase, is therefore strongly bound to myofibrillar structures of heart muscle, from which it can be released by treatment with hypotonic solutions. If the values given by Jacobs<sup>6</sup> for the partitioning of creatine kinase between mitochondria and cytoplasm in rat heart muscle are assumed to apply also to ox heart, it can be calculated that 100 g of heart tissue containing 13 per cent protein will contain about 1,800  $\mu$  of creatine kinase of which about 50 per cent will be extra-mitochondrial.

The original 800 g of heart tissue would therefore be expected to contain about 7,300  $\mu$  of extra-mitochondrial

enzyme. The original phosphate extract of the myofibrils contained about 2,000  $\mu$ , which amounts to 28 per cent of the estimated "cytoplasmic" enzyme in the tissue. The activity in the crystals was about 2 per cent of the "cytoplasmic" enzyme activity.

This work was carried out during the tenure of a Unilever European fellowship.

### Action of Pemoline on RNA Metabolism in the Brain

MAGNESIUM-PEMOLINE produces an increase of RNA in the brain tissue of animals<sup>1</sup>. It has been confirmed<sup>2,3</sup> that this product is a psycho-stimulant which acts on the memory. It has also been suggested<sup>4</sup> that RNA acts as a "molecule of memory" and that RNase interferes with this action in planarians<sup>5</sup> and in mammals<sup>6</sup>.

The sequence of atoms from the carbonyl group to the imino group in the pemoline molecule is planar and sterically similar to the corresponding zone of the cytosine and guanine molecules (Fig. 1A). Both these bases are components of nucleic acids, assumed in the Watson-Crick model to be bonded by three hydrogen bonds. This was confirmed in 1965 by Pauling and Corey<sup>7</sup>.

Fig. 1B shows the hydrogen bonds of the chelate structure of magnesium-pemoline (ref. 8 and others). This partial similarity in structure suggested to us the possibility that pemoline might be fixed to the active site of RNase in a manner similar to that described by Findlay *et al.*<sup>9</sup> for the RNA cytidine during enzymatic hydrolysis of RNA.

Our experiments were carried out either with crystalline pancreatic RNase or with homogenized and centrifuged rat and guinea-pig brain tissue. Yeast RNA was used as a

Fig. 1. A, Structure of pemoline (2-imino-5-phenyl-4-oxozolidinone); B, chelate structure of magnesium-pemoline (after Lange *et al.*<sup>8</sup>); C, possible interaction between pemoline and cytosine; D, pemoline and guanine. The shadowed line around the pemoline molecule in A represents the specific site of RNase, as suggested by Findlay *et al.*<sup>9</sup> to explain the mechanism of RNase activity.

Table 1

Assay	pH	None	With pemoline	Inhibition (per cent)	With magnesium-pemoline	Inhibition (per cent)
(A) Action on crystalline pancreatic RNase	—	5.0	0.036	0.023	36	—
(B) Action on brain RNase	Rat	5.4	0.125	0.119	5	0.061
	Rat	7.4	0.094	0.075	20	0.045
	Guinea-pig	5.4	0.084	0.076	10	0.067
	in vitro	7.4	0.200	0.126	37	0.036
(C) Action on brain RNase	Rat	5.4	0.192	—	—	0.090
	Rat	7.4	0.040	—	—	0.025
	Guinea-pig	5.4	0.075	—	—	0.066
	in vitro	7.4	0.090	—	—	0.070

(A) Determination by spectrophotometric method<sup>12</sup>. Results given in E/min at 300 $\mu$ . Final concentration of mixed solution: pemoline  $7.5 \times 10^{-4}$  moles; pancreatic RNase, 3.75 mcg/ml. Yeast RNA (purified, free from RNase) 0.1 per cent. Pemoline was prepared according to Traube and Ascher<sup>13</sup>; RNase was made by us from beef pancreas. The purity constants are described by Ledoux<sup>16</sup>.

(B) Recently excised brain tissue was homogenized (1:10) either in barbiturate (pH 7.4) or acetate (pH 5.4) buffer and then centrifuged at 525 g for 3 min. The assay for RNase activity was performed according to McDonald<sup>17</sup>. 5 ml. supernatant and 6 ml.  $3 \times 10^{-3}$  molar pemoline or, in some cases, magnesium-pemoline (in the blank run, 6 ml. buffer instead) were mixed and pre-incubated for 30 min at 37° C. Afterwards, 1 ml. of 0.5 per cent yeast RNA was added. After standing for another 30 min periodic samples were precipitated with McFadyen's reagent, and the extinctions of the filtrates read at 260 $\mu$ .

(C) Groups of six animals were injected intraperitoneally with 100 mg/kg of magnesium-pemoline suspended in saline (controls were run with saline only) and killed after 2 h. RNase activity on brain tissue was assayed by the method of Kunitz (*loc. cit.*)<sup>14</sup> and by Datta *et al.*<sup>15</sup>, as explained above (B).

substrate. Table 1A shows the results obtained with pancreatic RNase. It may be seen that pemoline produced a significant inhibition. The slight solubility of pemoline and of the corresponding magnesium chelate did not allow us to use higher concentrations of the drug. On the other hand, we did not think DMSO suitable for use as a solvent<sup>1</sup> because it is known to induce changes in cell wall permeability<sup>10</sup>, and also to liberate RNase from the lysosomes<sup>11</sup>. The inhibitory action on RNase of magnesium alone has long been known<sup>12,13</sup> and, although not shown in the table, magnesium-pemoline was also a powerful inhibitor.

The *in vitro* inhibition of alkaline and acid RNase of rat and guinea-pig brain tissue by pemoline and magnesium-pemoline is shown in Table 1B. The decrease in brain RNase activity after two hours of treatment with magnesium-pemoline *in vivo* can be seen in Table 1C.

The ultra-violet spectra of pemoline ( $4 \times 10^{-5}$  moles/l.), RNA (0.004 per cent), and a mixture of the two, at pH = 5.0, have been studied. No shifting of the maximum at 260 $\mu$  was observed; the A260 of the mixture, however, was significantly lower (10.5 per cent) than the sum of the individual components.

In order to investigate whether the observed difference could be attributed to a partial hydrolysis of RNA, another experiment was carried out in which RNA was incubated at pH 8.0 in the absence and presence of pemoline. The results shown in Table 2 suggest an interaction between pemoline and RNA; however, no significant alteration in the rate of hydrolysis of RNA was observed. Furthermore, consideration of the steric characteristics of the pemoline molecule suggests that pemoline may be fixed to the cytosine or guanine residues in the RNA chain. This possibility is illustrated in Fig. 1C and D.

Glasky and Simon<sup>1</sup> reported that pemoline increases RNA polymerase activity. This fact is not inconsistent with our finding that RNase is inhibited by pemoline and magnesium-pemoline, because it is well known that different enzymes react in different ways; there are several

Table 2

Samples at pH 8	Time (in min) at 37° C			
	0	30	60	240
Pemoline ( $4 \times 10^{-5}$ moles/l.)	0.211	0.220	0.220	0.220
RNA (0.004 per cent)	0.314	0.332	0.353	0.360
Pemoline + RNA ( $4 \times 10^{-5}$ moles/l. and 0.004 per cent)	0.333	0.358	0.368	0.379

At known intervals, portions were removed and added to a similar volume of McFadyen reagent. The solutions were centrifuged and the extinctions of the supernatants read at 260 $\mu$ .

chemical and physical agents which bring about opposing reactions in RNA-polymerase and RNA-depolymerase or RNase (for example, magnesium ions<sup>12,13,18</sup>, freezing and thawing<sup>12,19</sup>, radiation<sup>20,21</sup>, actinomycin<sup>22,23</sup>, etc.).

The biochemical and pharmacological properties of pemoline seem to be due to an increase in the concentration of brain RNA. This increase in RNA may be the result of enhanced biosynthesis, or diminished degradation, or both. Our results suggest that decreased degradation may be due to inhibition of RNase or stabilization of the RNA configuration.
